

Collective Behavior in Heavy Ion Collisions

Constantin Loizides
(LBNL/EMMI)

28 July 2011

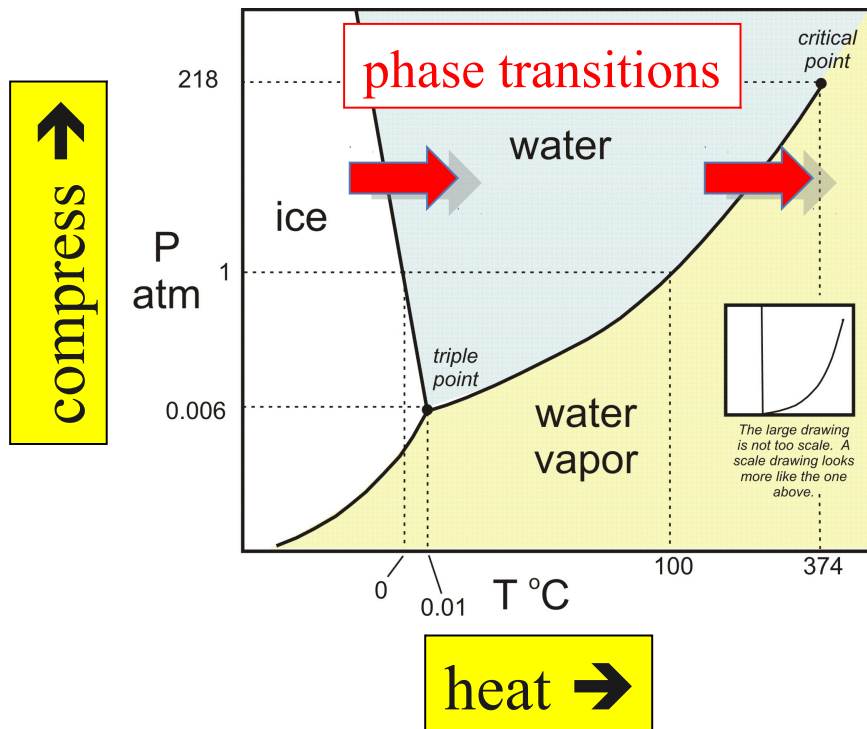

The 19th Particle and Nuclei International Conference, MIT, Cambridge, MA, USA

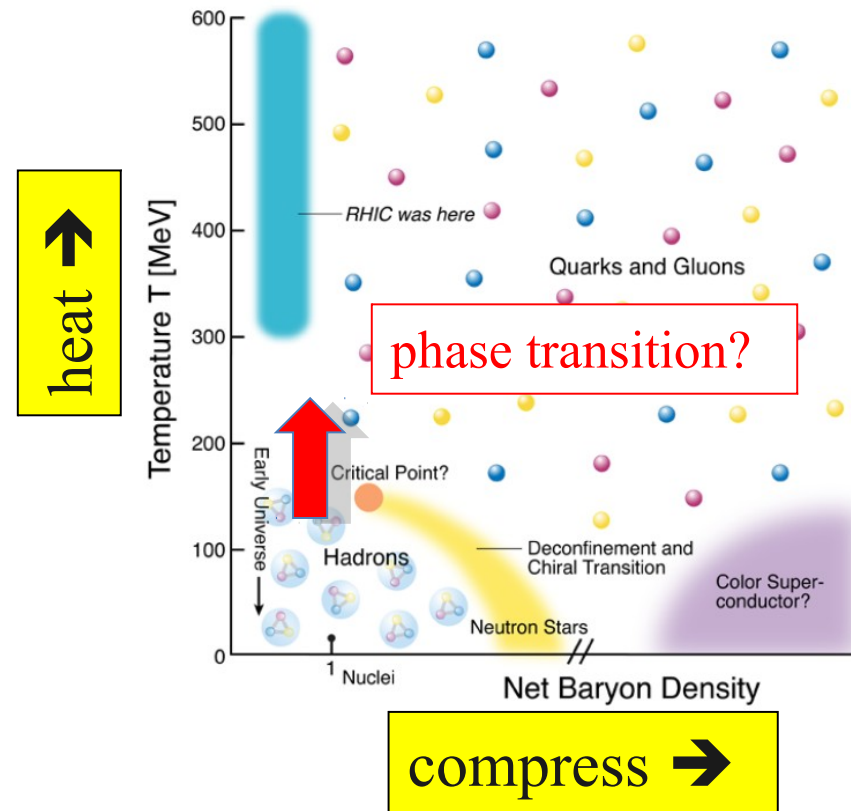

Study hot QCD matter

2

Phase diagram of water
(simplified)

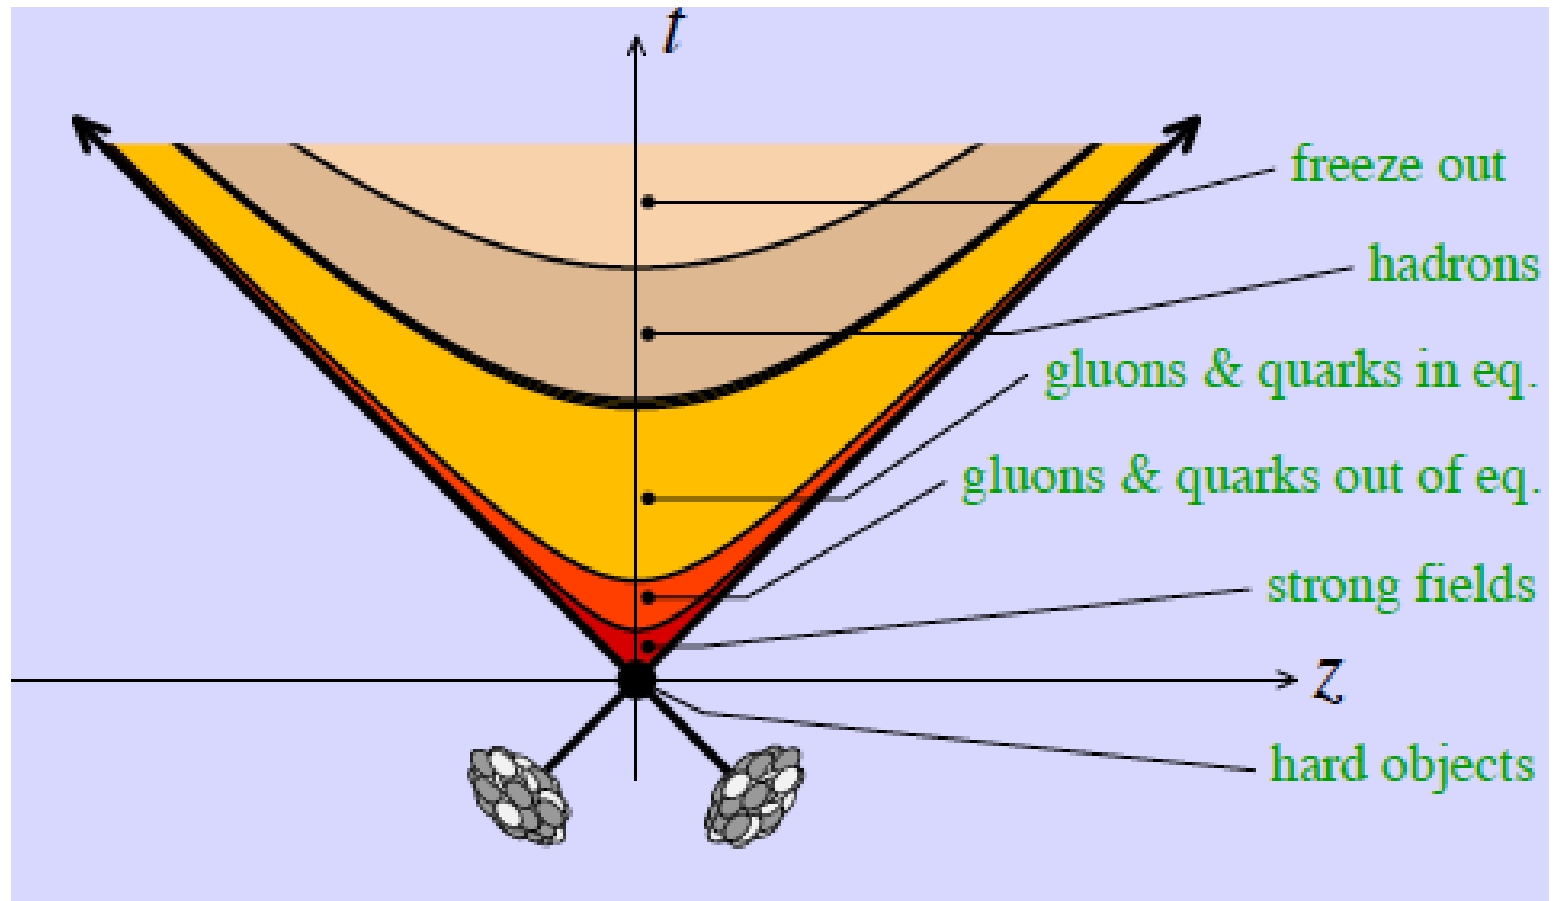

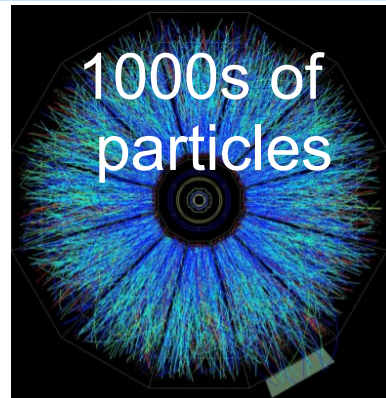

Phase diagram of QCD
(simplified)

Experimental study of QCD phase diagram by:
colliding nuclei head-on to convert cold
nuclear matter into a fireball of partons

Complex collision dynamics

3

Studying matter in the laboratory

4

Changing initial conditions:

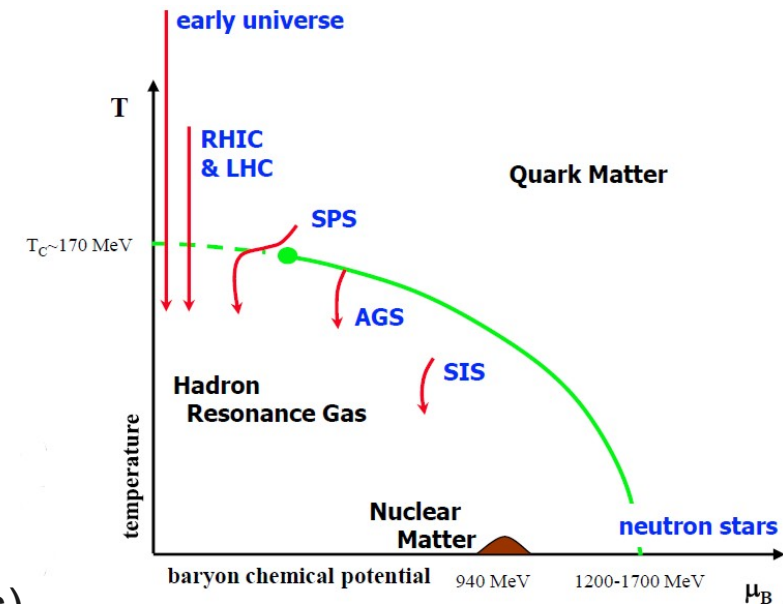

Ideal

Temperature Matter Density

Practical

Species Energy Size Shape

Centrality (#Participants)

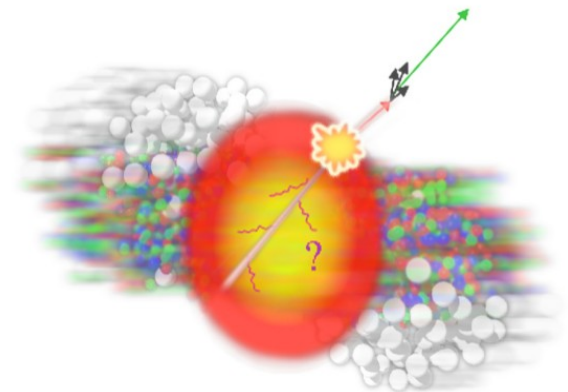

Probing the matter microscopically:
(Hard probes, C.Salgado next)

Ideal

Microscopy Tomography

Practical

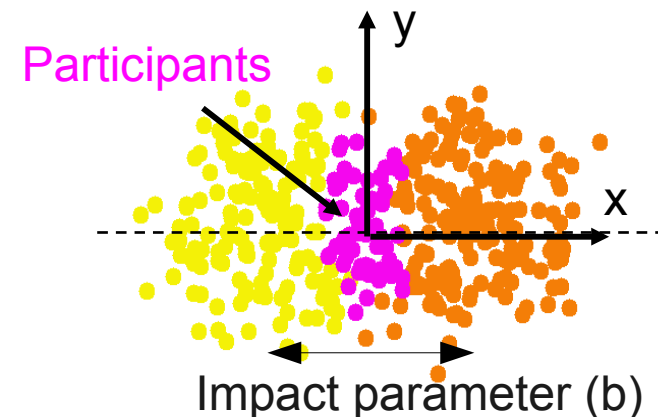

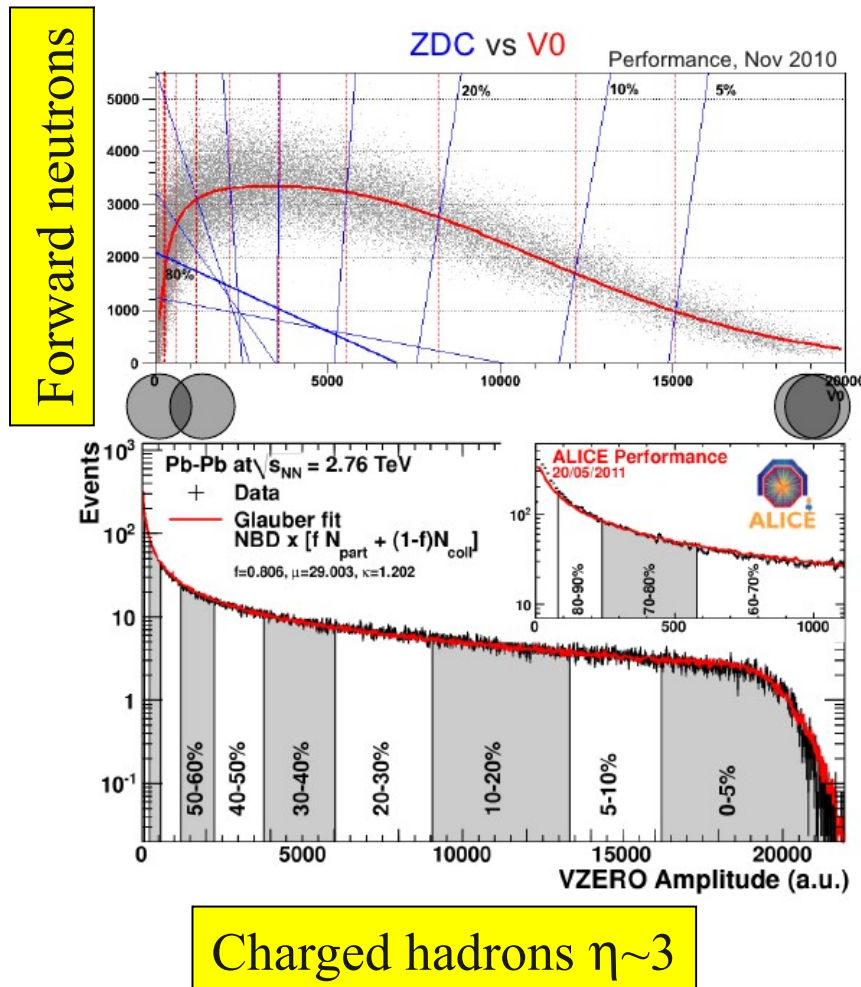

Jets Photons Quarkonia

Nuclear geometry and collision centrality 5

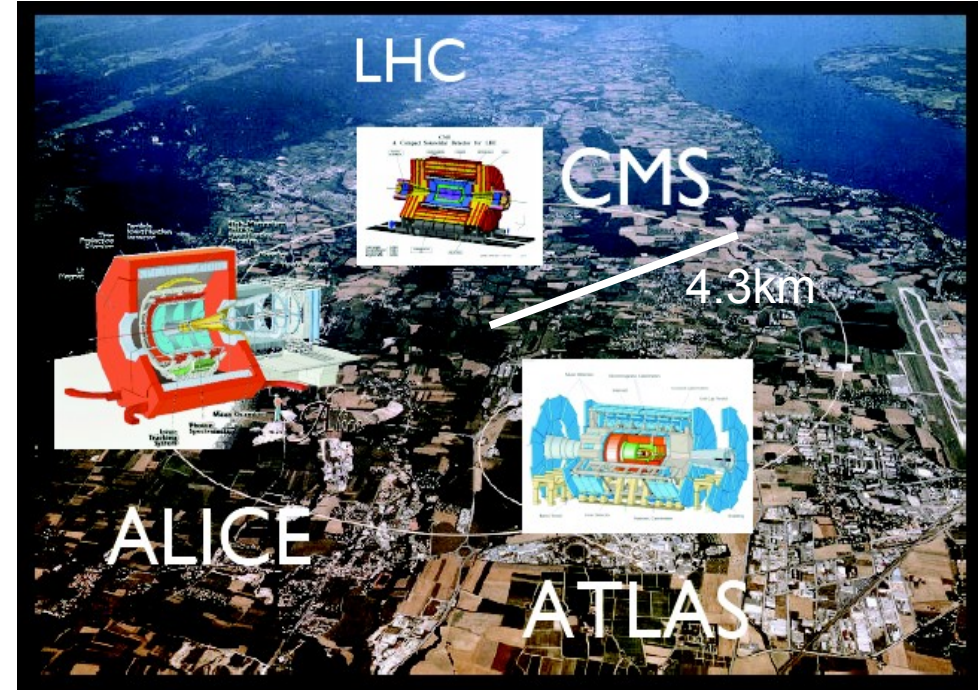

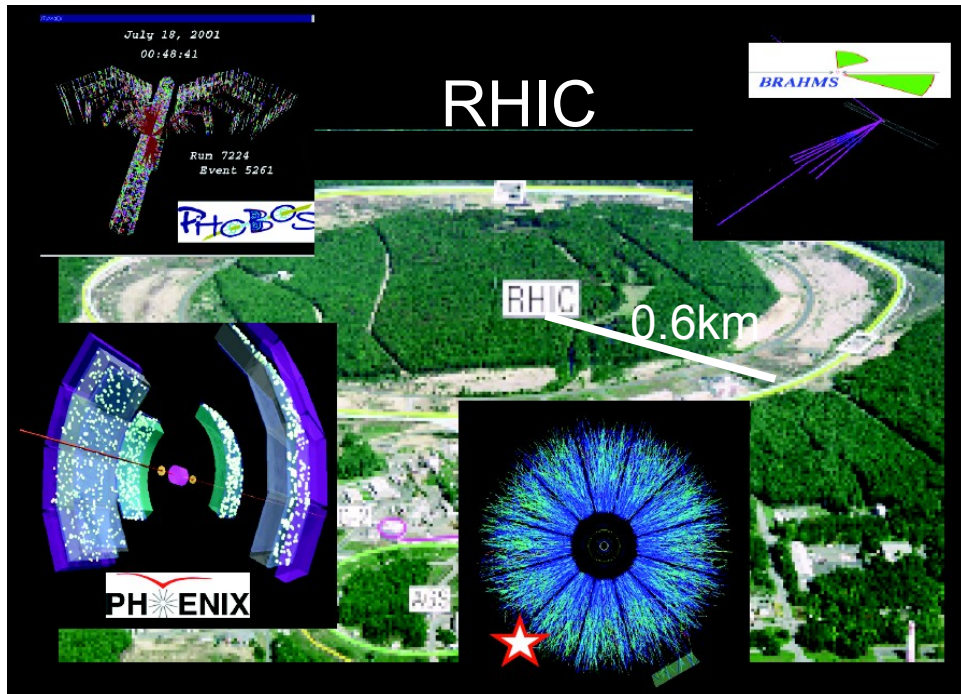

Nuclei are “macroscopic”:
Characterize collisions by
impact parameter

- Correlate yields from disconnected parts of phase space
 - Correlation arises from common dependence on collision impact parameter
- Order events by centrality metric
 - Typically, classify them as “ordered” fraction of total cross section
 - eg. 0-5% most central
- Number of participants (volume)

Heavy ion experiments at RHIC/LHC

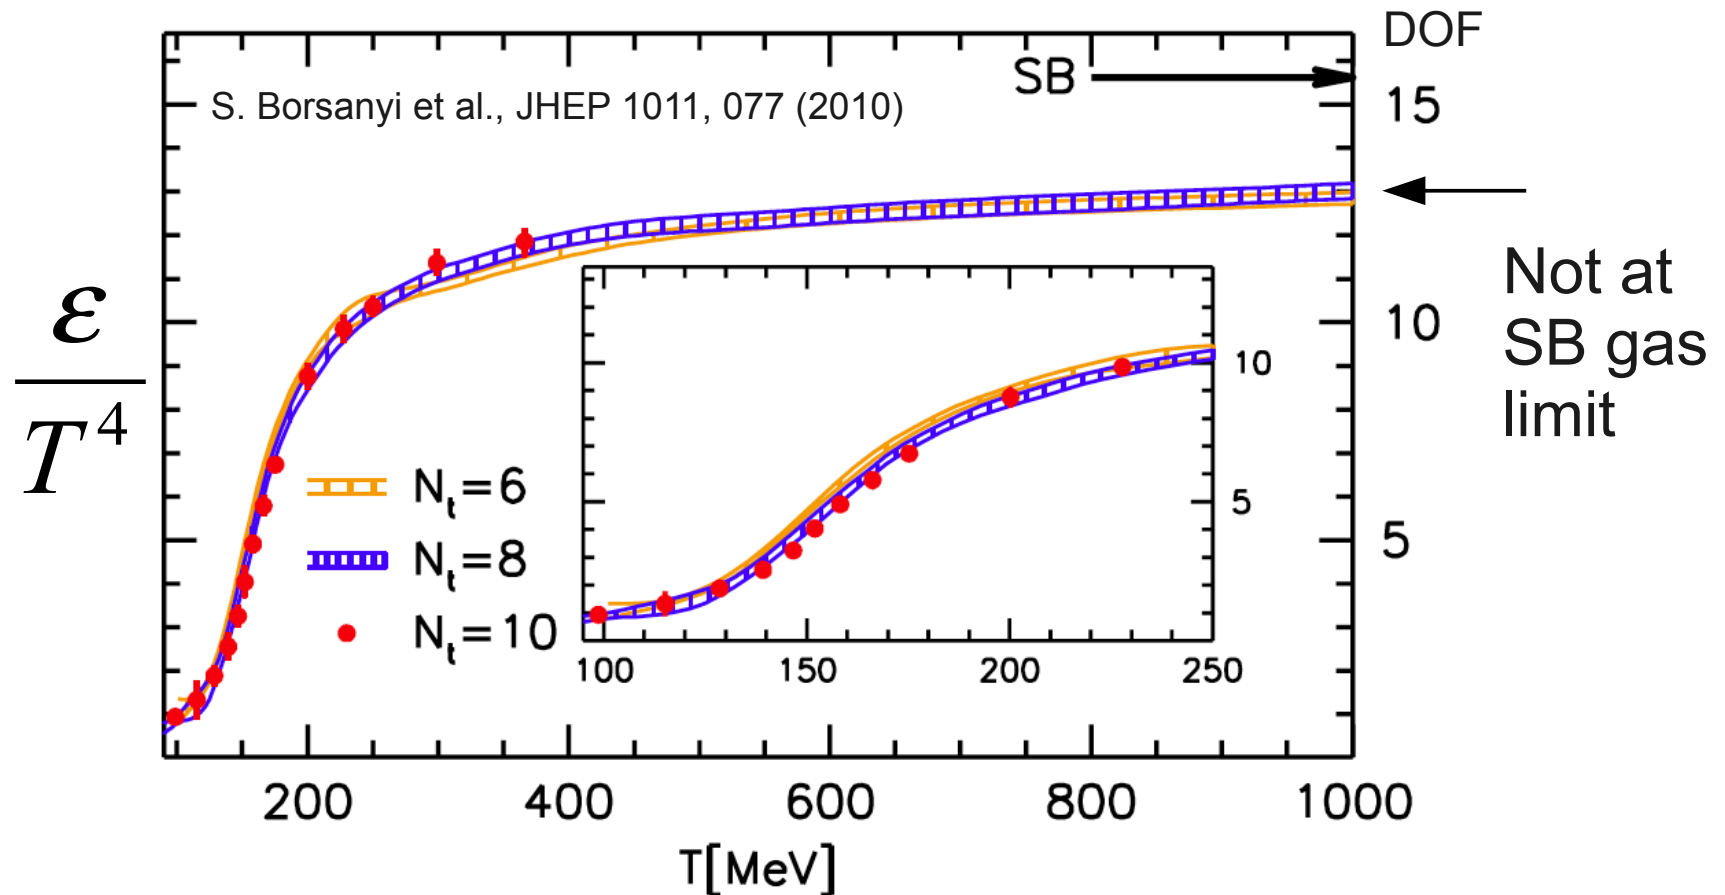

6

- RHIC: First beams June 2000
 - p+p, d+Au, Cu+Cu, Au+Au (~20, 62.4, 130, 200 AGeV)
 - 2 multipurpose (PHENIX, STAR) and 2 specialized (BRAHMS, PHOBOS) experiments
 - >2006, only STAR and PHENIX
 - Beam energy scan (2010/11)
- LHC: First beams in Nov 2009
 - p+p (900, 2.36, 2.76, 7 TeV)
 - Pb+Pb at 2.76 ATeV in Nov 2010
 - 1 dedicated HI experiment
 - Mid-rapidity, low mass, PID
 - 2 large HEP experiments
 - Large acceptance, full calorimetry

QGP cross-over phase transition

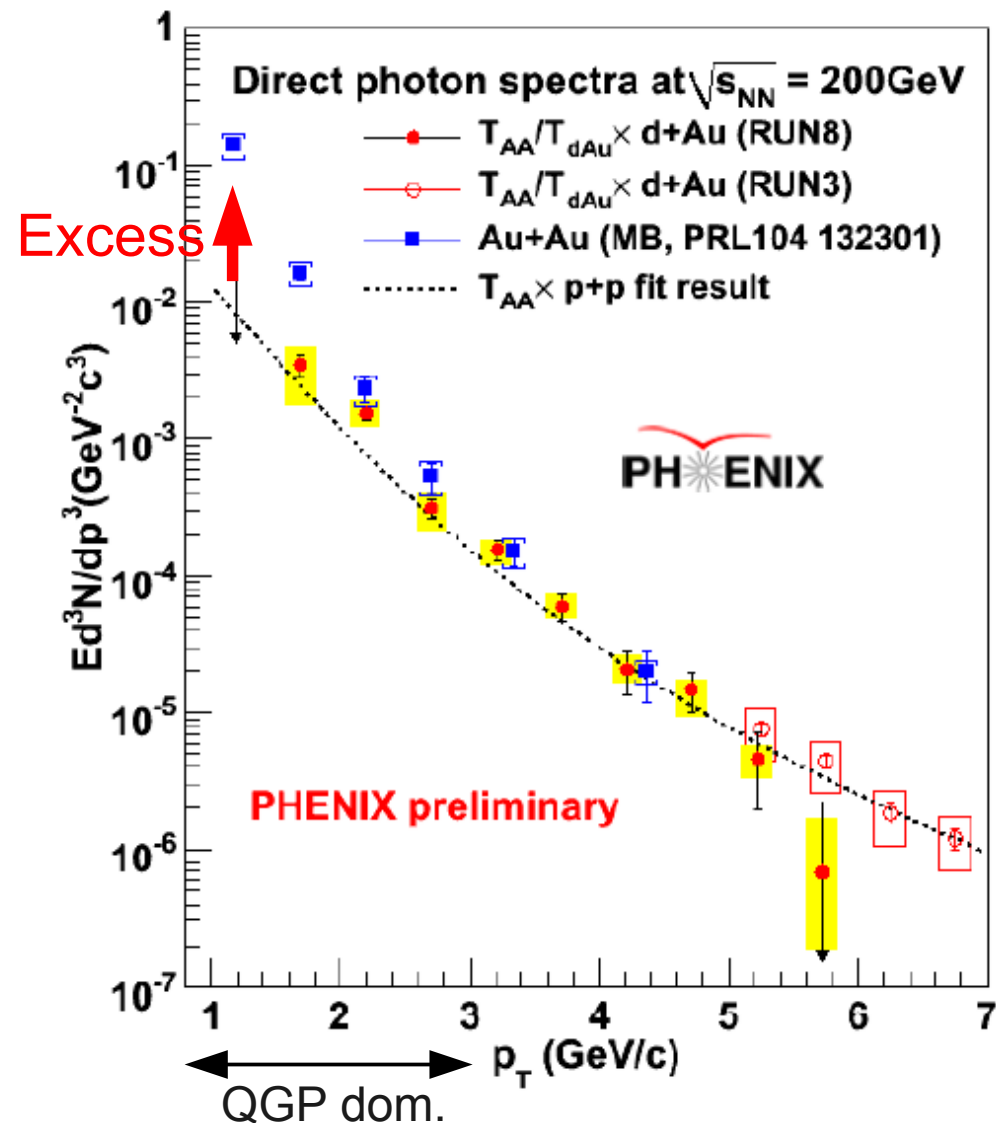

7

Lattice predicts a cross-over phase transition
from hadronic to partonic degrees of freedom

$$T_c \approx 145-175 \text{ MeV}$$
$$\epsilon_c \sim 1 \text{ GeV/fm}^3$$

Direct photons: No charge, no color, ie. they do not interact
Emission over all lifetime convolution of all T

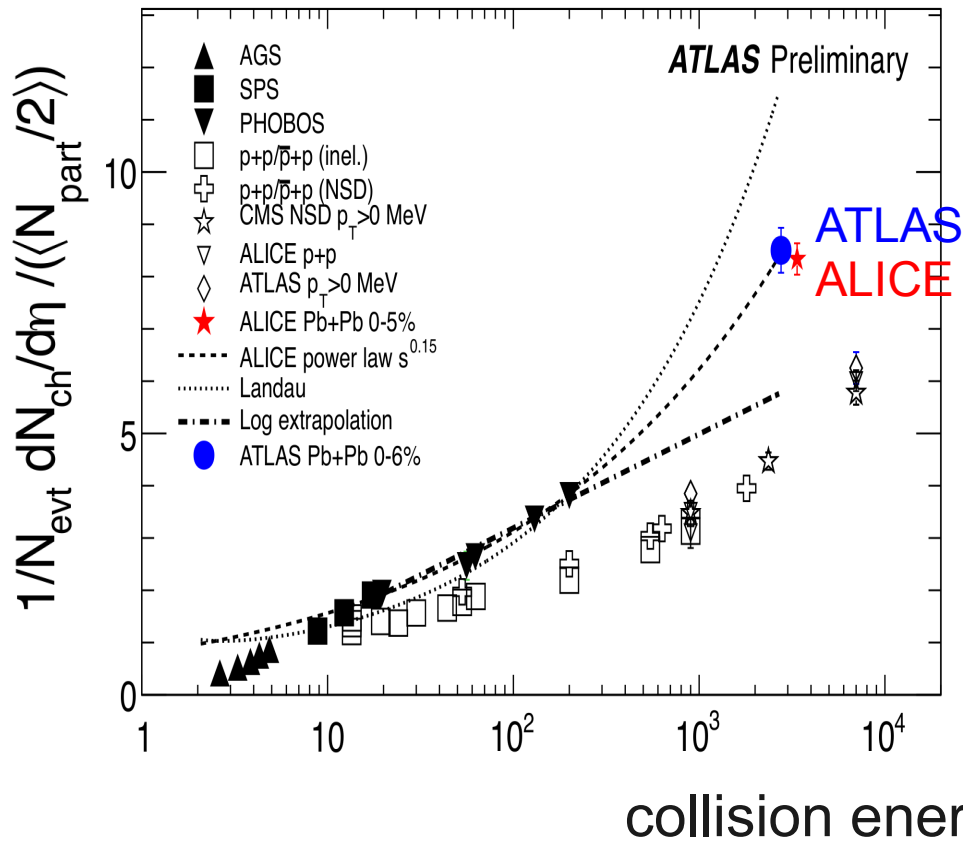

- Exponential (thermal) shape with $T \sim 200$ MeV
- No excess in d+Au data
- Emission rate and shape consistent with that from equilibrated matter
- $T_{hydro} = 300 - 600$ MeV ($> 2 T_c$)

First experimental observation of $T > T_c$

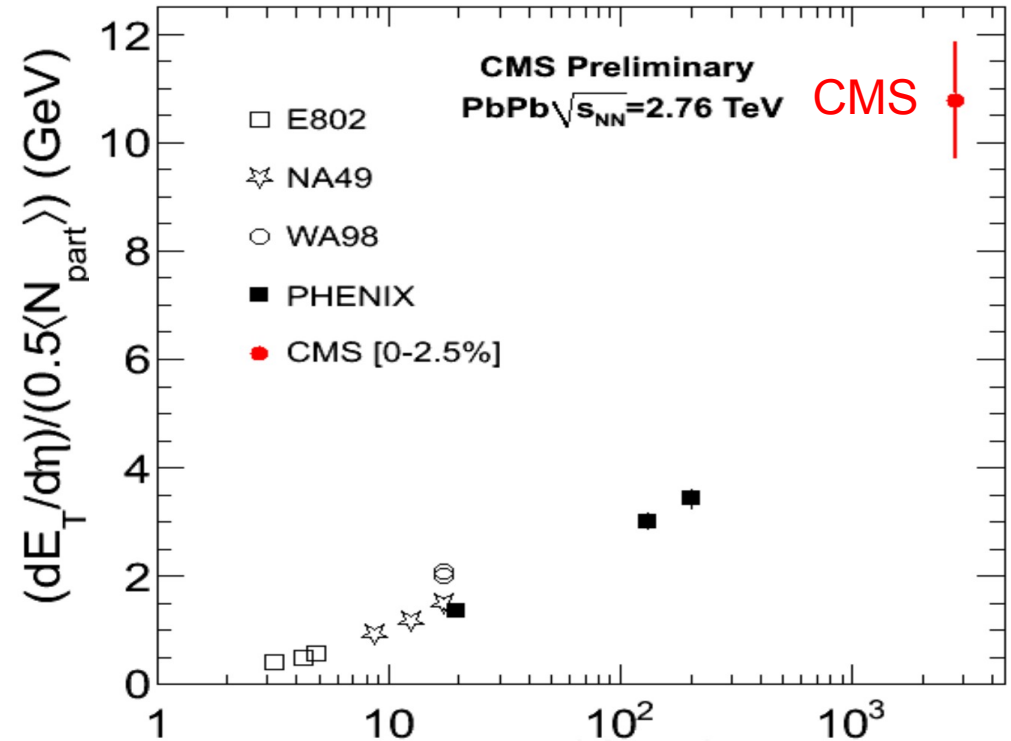

What do we know already from LHC?

9

Charged-particle density

Transverse energy density

Compared to top RHIC energy

- x2.1 increase in $dN_{\text{ch}}/d\eta$ (x1.9 to pp)
- x2.5-3 times larger energy density
- Midrapidity $dE_T/d\eta \sim 2$ TeV at LHC

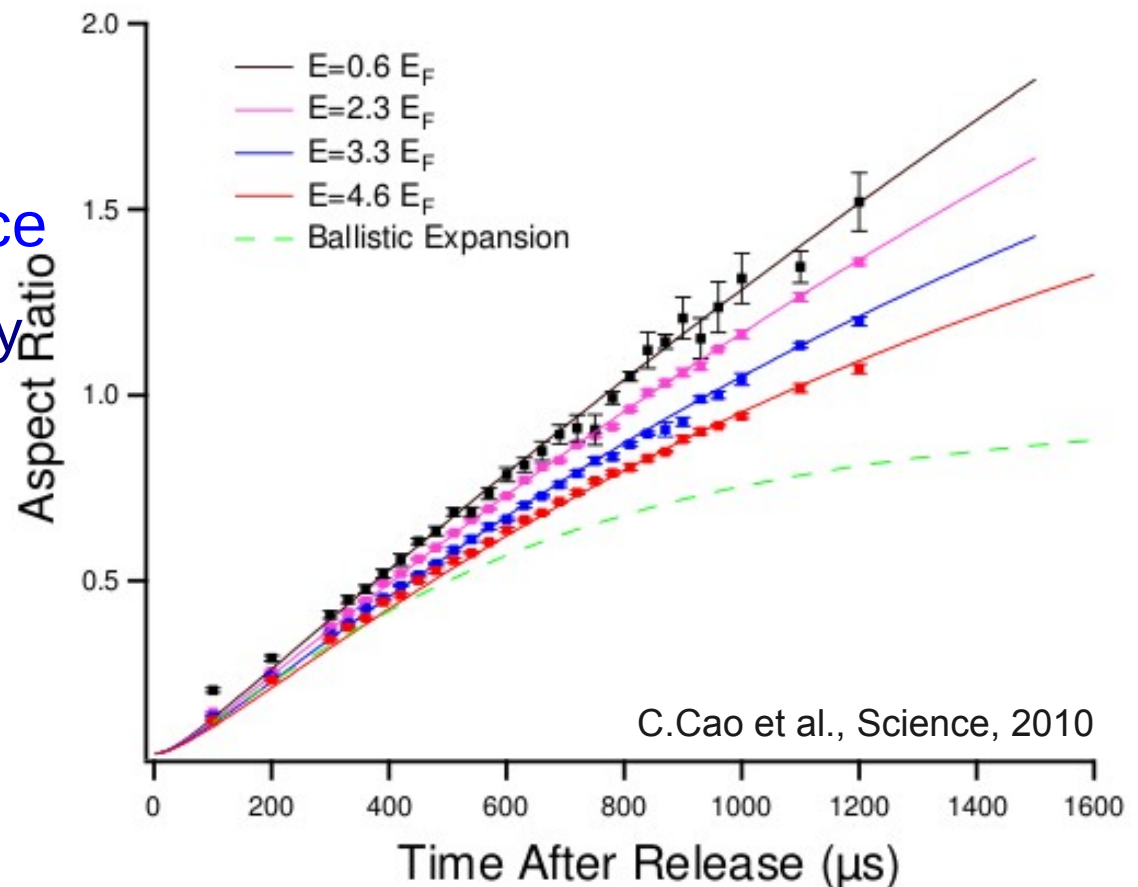

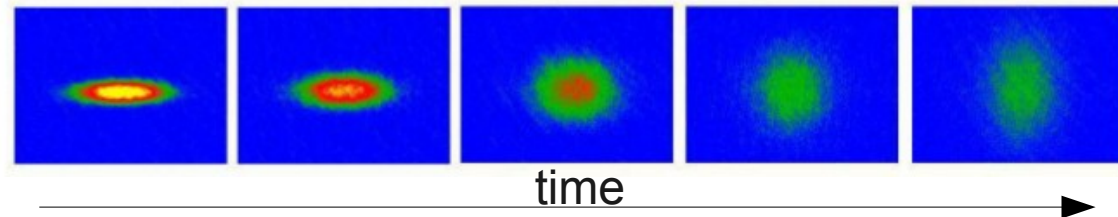

$$\tau \epsilon_{LHC} \geq 3 \times \tau \epsilon_{RHIC}$$

How can we prove we make matter?

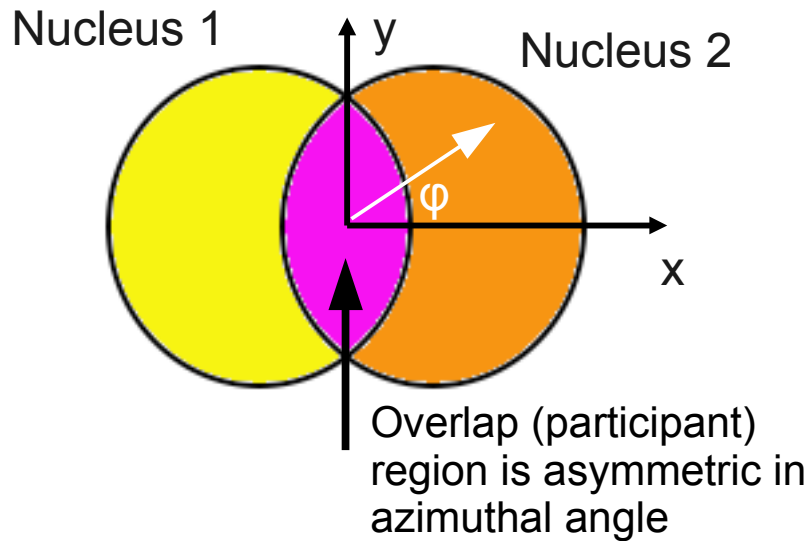

10

Ultracold Fermionic Atom Fluid (^6Li)

- Optically trapped atoms
 - Degenerate Fermi gas
 - NanoKelvin temperature
- Interactions magnetically tuned to Feshbach resonance
 - Unitary limit: Largest 2-body scattering cross section
 - “Strongly-coupled” system
- Prepare system with spatial anisotropy
 - Develops momentum anisotropy
 - Analysis of spatial profile

Initial spatial anisotropy

Eccentricity

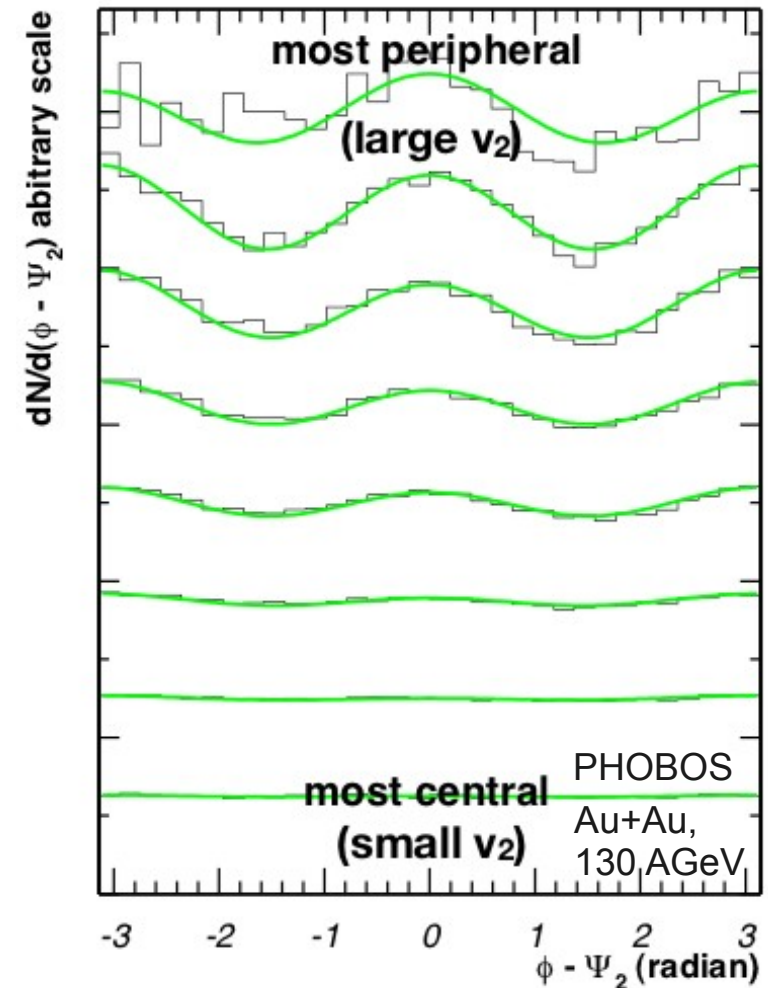

$$\varepsilon = \frac{\langle y^2 \rangle - \langle x^2 \rangle}{\langle y^2 \rangle + \langle x^2 \rangle}$$

Interactions
present early

Elliptic flow

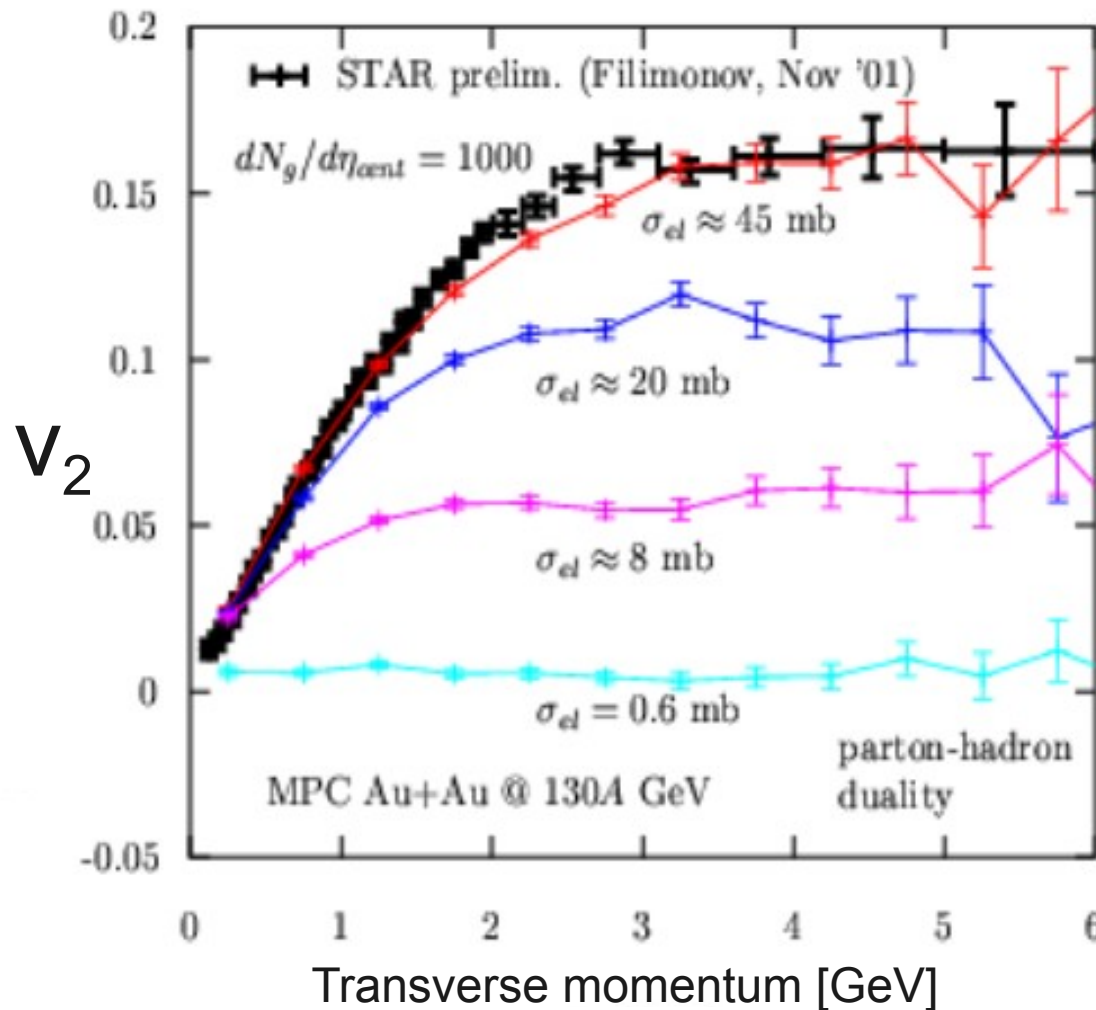

$$v_2 = \frac{\langle p_x^2 \rangle - \langle p_y^2 \rangle}{\langle p_x^2 \rangle + \langle p_y^2 \rangle}$$

Final momentum anisotropy

$$\frac{dN}{d\phi} \sim 1 + 2v_2 \cos[2(\phi - \psi_R)] + \dots$$

What's needed partonically to get v_2 ? 12

Parton transport model:
Boltzmann equation with
2-to-2 gluon processes

D.Molnar, M.Gyulassy
NPA 697 (2002)

HUGE cross sections
needed to describe v_2

Need large opacity to describe elliptic flow, ie elastic parton cross sections as large as inelastic the proton cross-section.

Ideal relativistic hydrodynamics

$$T^{\mu\nu} = (e + p)u^\mu u^\nu - p g^{\mu\nu}$$

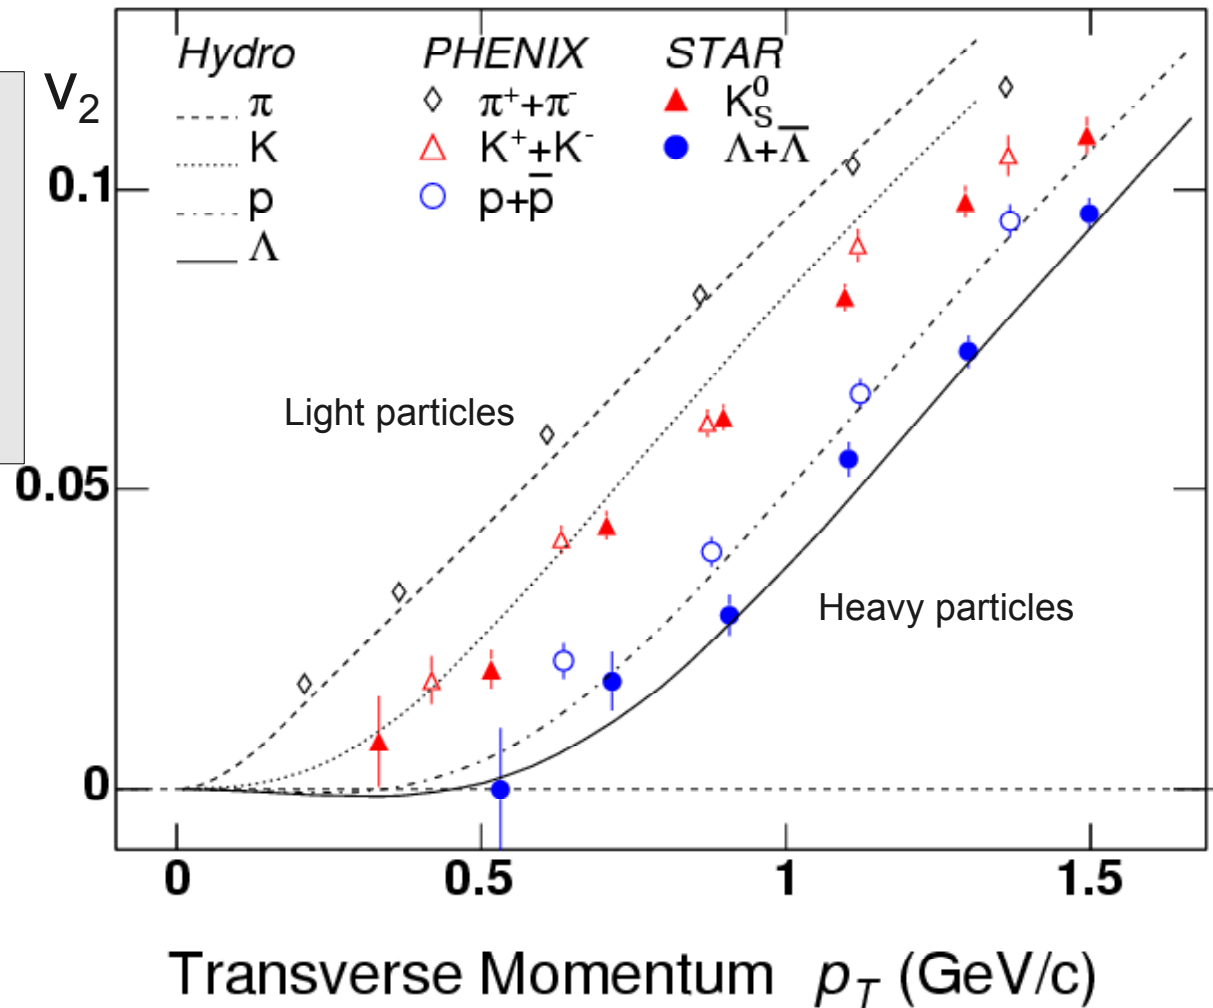

$$\delta_\mu T^{\mu\nu} = 0$$

$$\delta_\mu N_i^\mu = 0, \quad i = B, S, \dots$$

$$p = p(e, n) \quad \text{Closure with EoS}$$

Assumption:

After a thermalization time ($\leq 1 \text{ fm}/c$) a system in **local equilibrium** with zero mean free path and zero viscosity is created

Initial conditions (IC) \longrightarrow

Perfect fluid?

Shear viscosity in QCD

14

Analytic: Csernai, Kapusta and McLerran PRL 97, 152303 (2006)

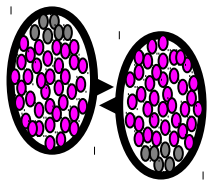

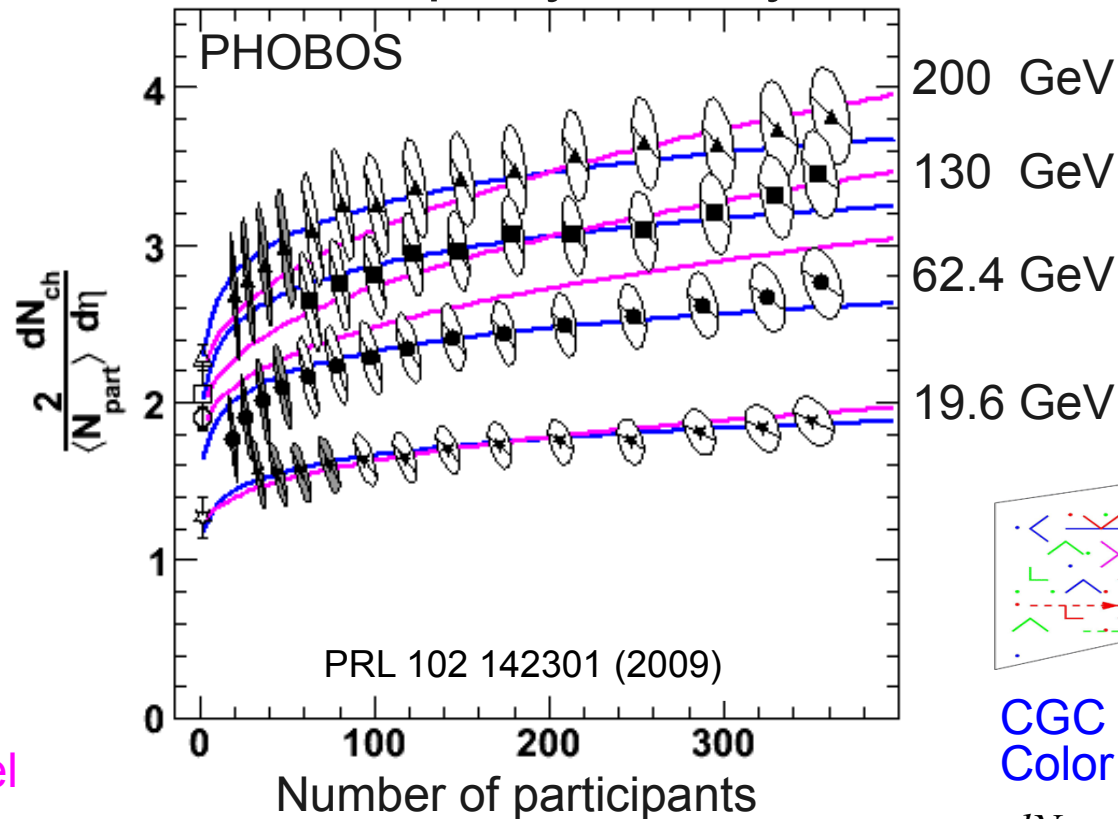

Lattice: H. Meyer, PR D76, 101701R (2007)

$$\frac{\eta}{s} = \frac{1}{4\pi}$$

For a large class
of holographic duals
(see A.Karch Wed plen.)

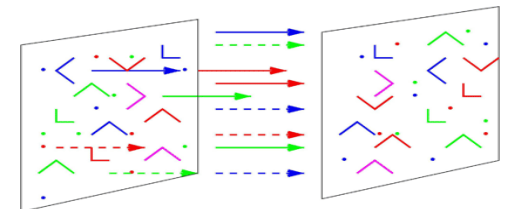

Mid-rapidity density

Glauber IC
Two-component model

$$\frac{dN}{d\eta} = \frac{dN}{d\eta_{\text{pp}}} ((1-x) N_{\text{coll}} + x N_{\text{part}}/2)$$

PRC 70 021902 (2004)

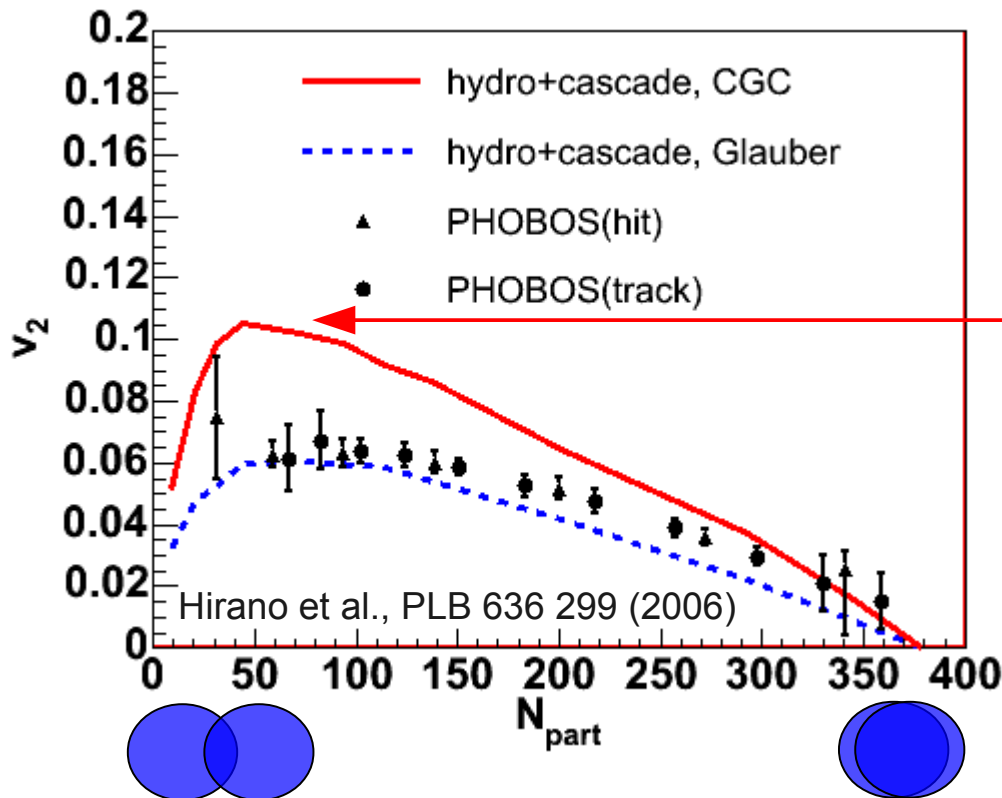

CGC IC
Color glass condensate

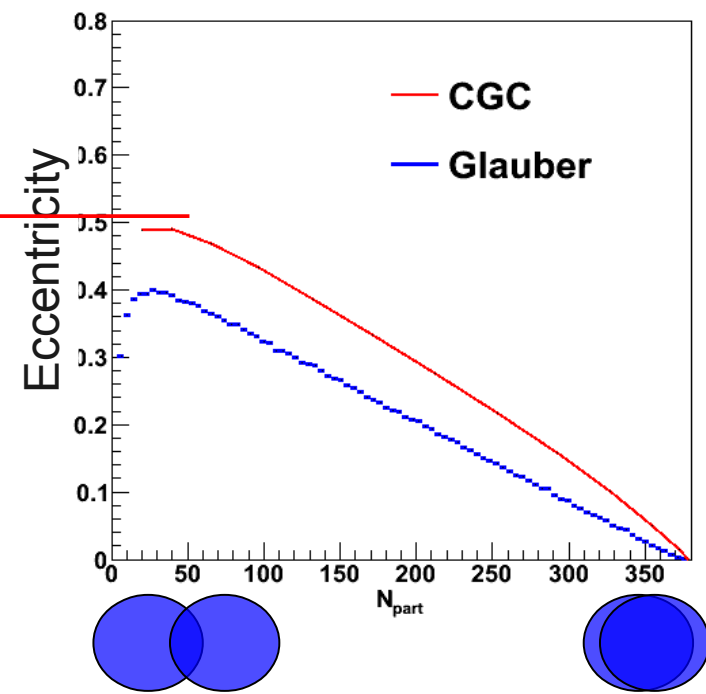

$$\frac{dN}{d\eta} \propto N_{\text{part}}^{\alpha} \sqrt{s}^{\lambda}$$

PRL 94 022002 (2005)

Two classes of models describe the multiplicity
(believed to be sensitive to initial state) equally well

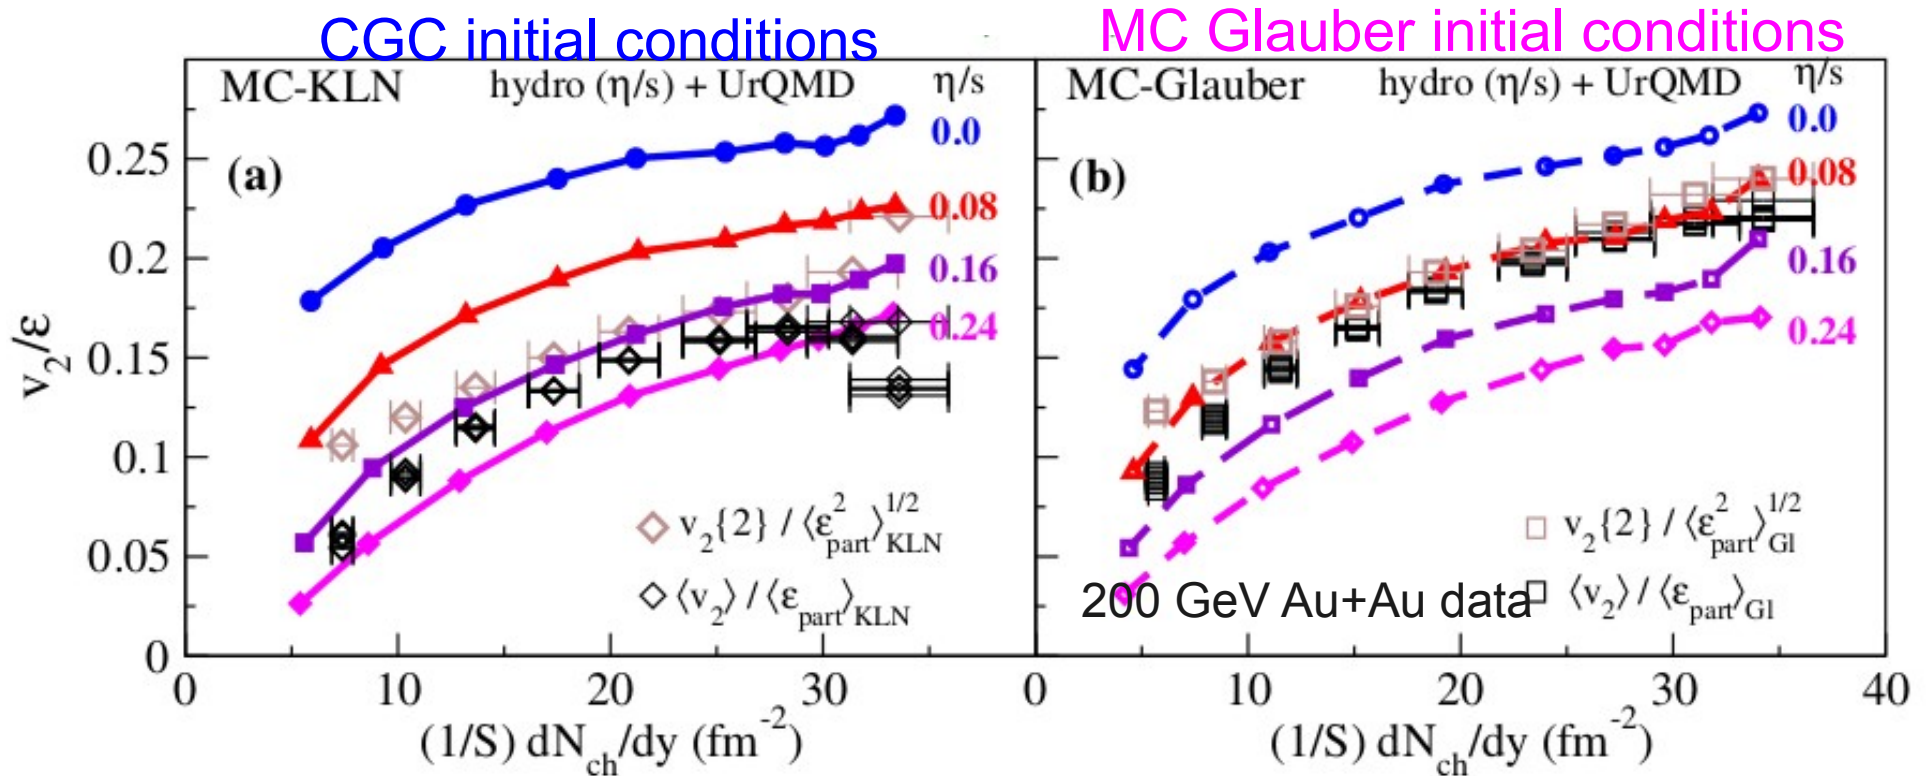

Higher eccentricity leads to higher flow

Ambiguity in description of initial state allows for various models:
Size of viscous corrections and/or soft equation of state?

The hot QGP is a nearly perfect fluid ... 17

Combination of many calculations, including state-of-art results from Israel-Stewart theory for a conformal fluid (2+1D), hint to a low shear viscosity to entropy ratio:

$$\frac{1}{4\pi} < \frac{\eta}{s} < \frac{3}{4\pi}$$

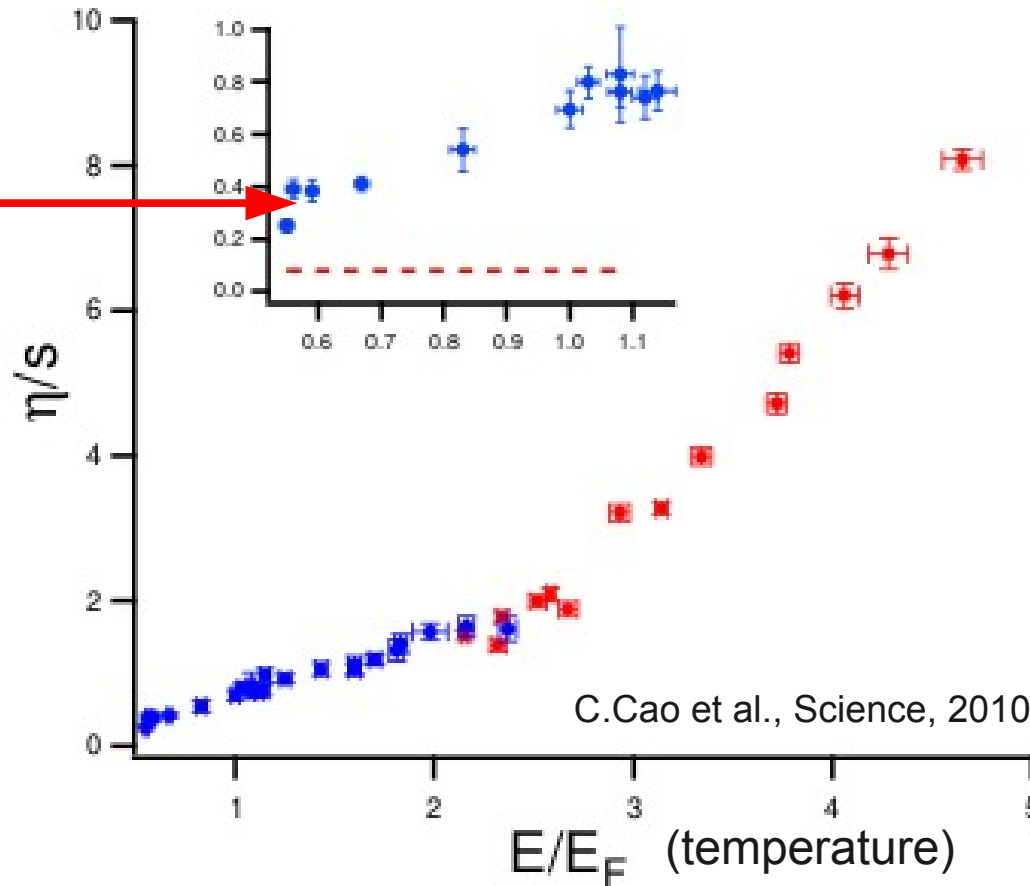

Largest part of uncertainties still from the ambiguity in the description of initial state.

... as are the ultracold atoms!

18

Ultracold Fermionic Atom Fluid (${}^6\text{Li}$)

$$\frac{\eta}{s} \leq \frac{5}{4\pi}$$

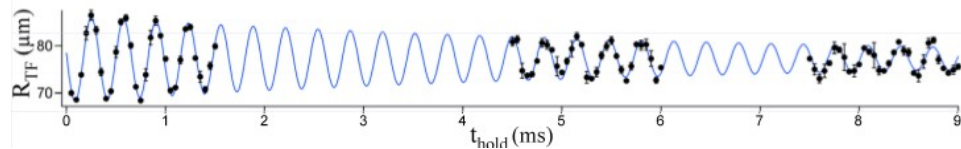

C.Cao et al., Science, 2010

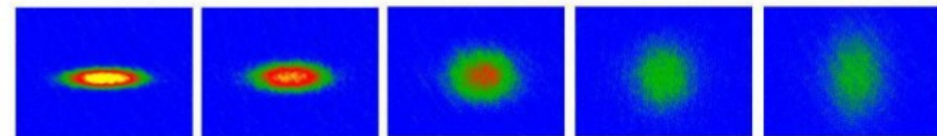

$T=0.1\text{neV}$
(QGP $\sim 0.3\text{TeV}$)

Schaefer/
Cao Mon 1K

Low temperature: Breathing mode

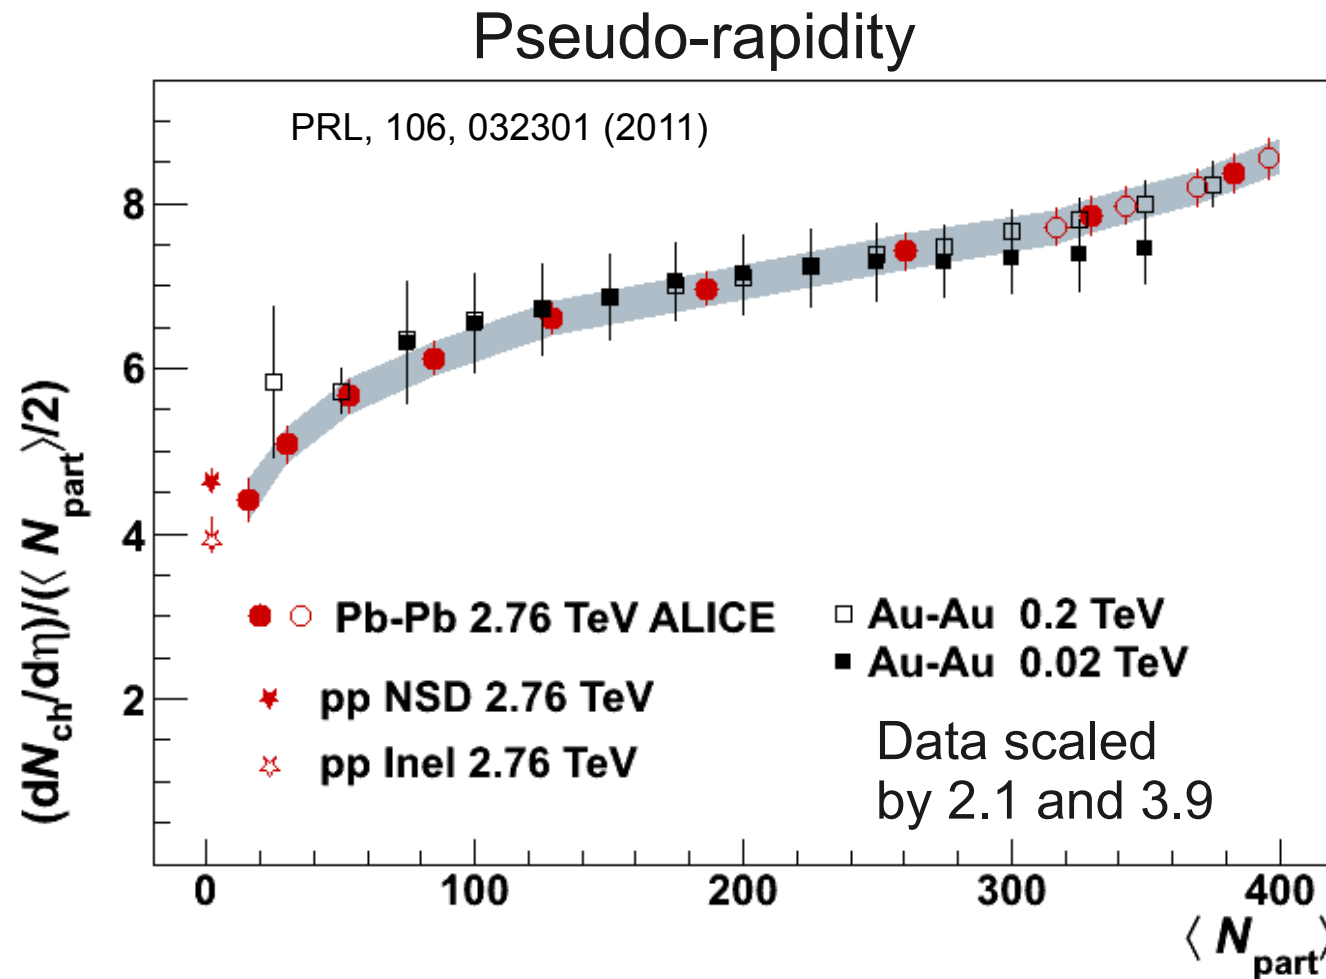

High temperature: Elliptic flow

Does the picture change at the LHC?

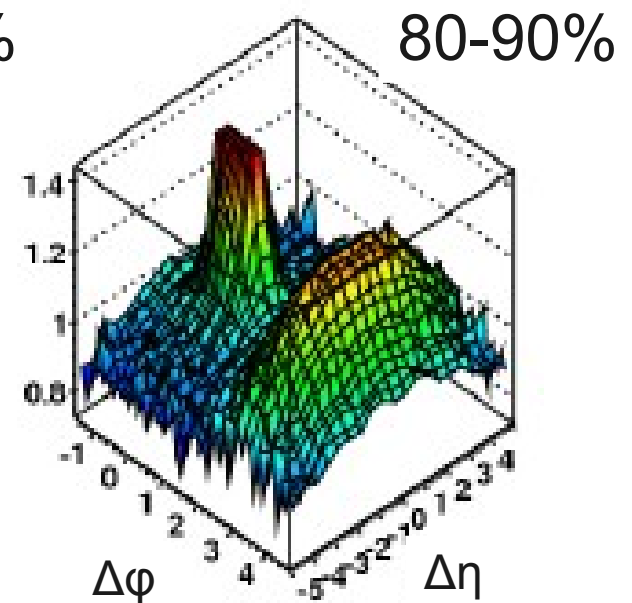

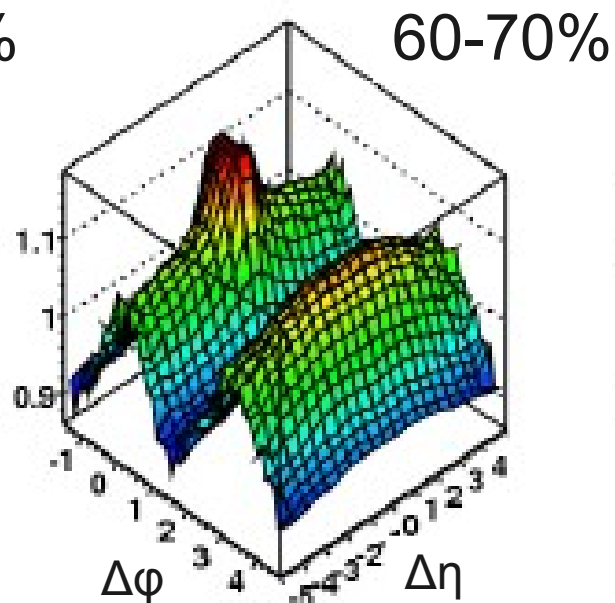

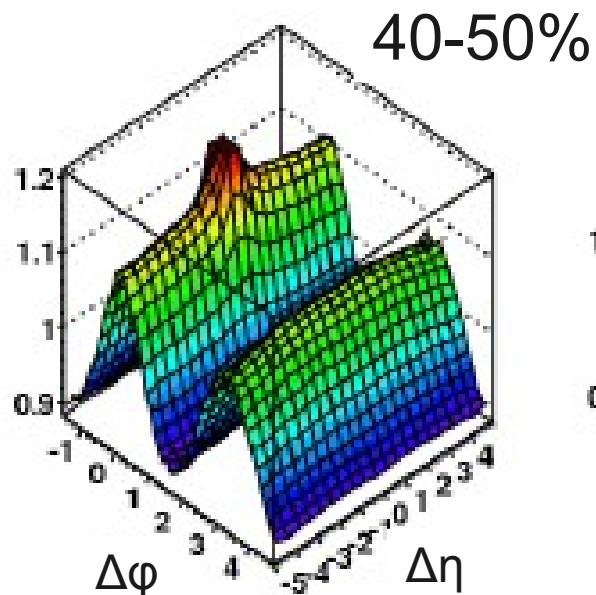

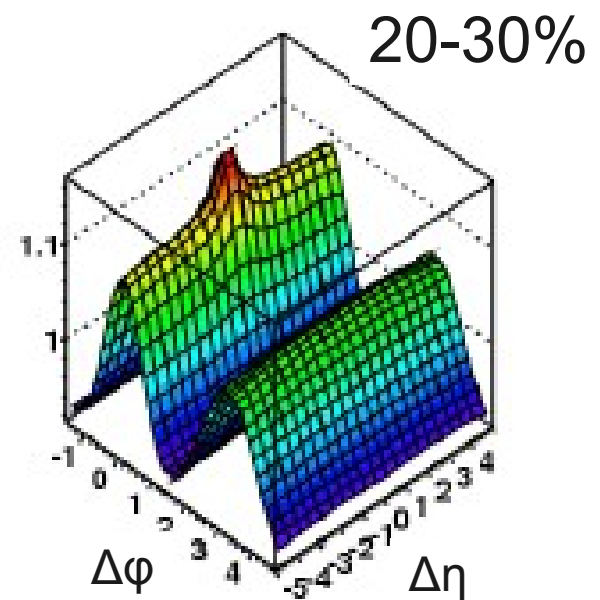

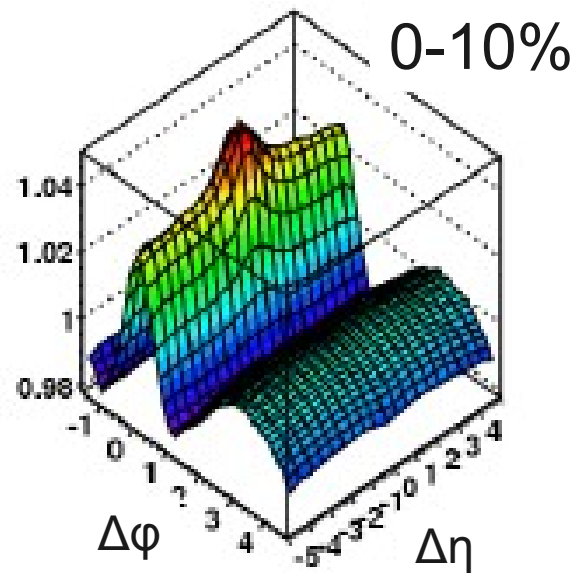

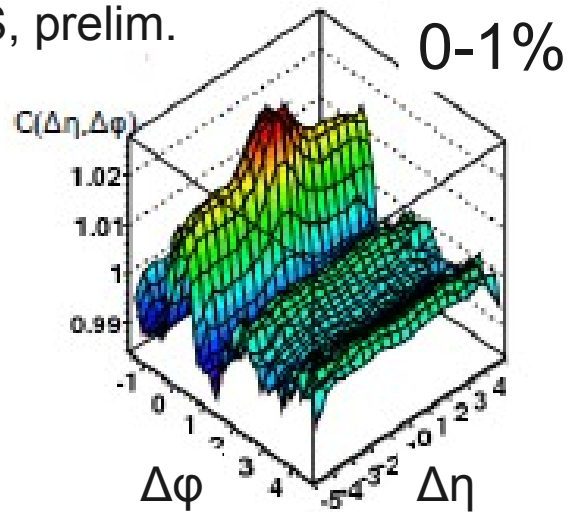

19

Striking similarities between data over about two orders of collision energy. Factorization into energy and centrality.

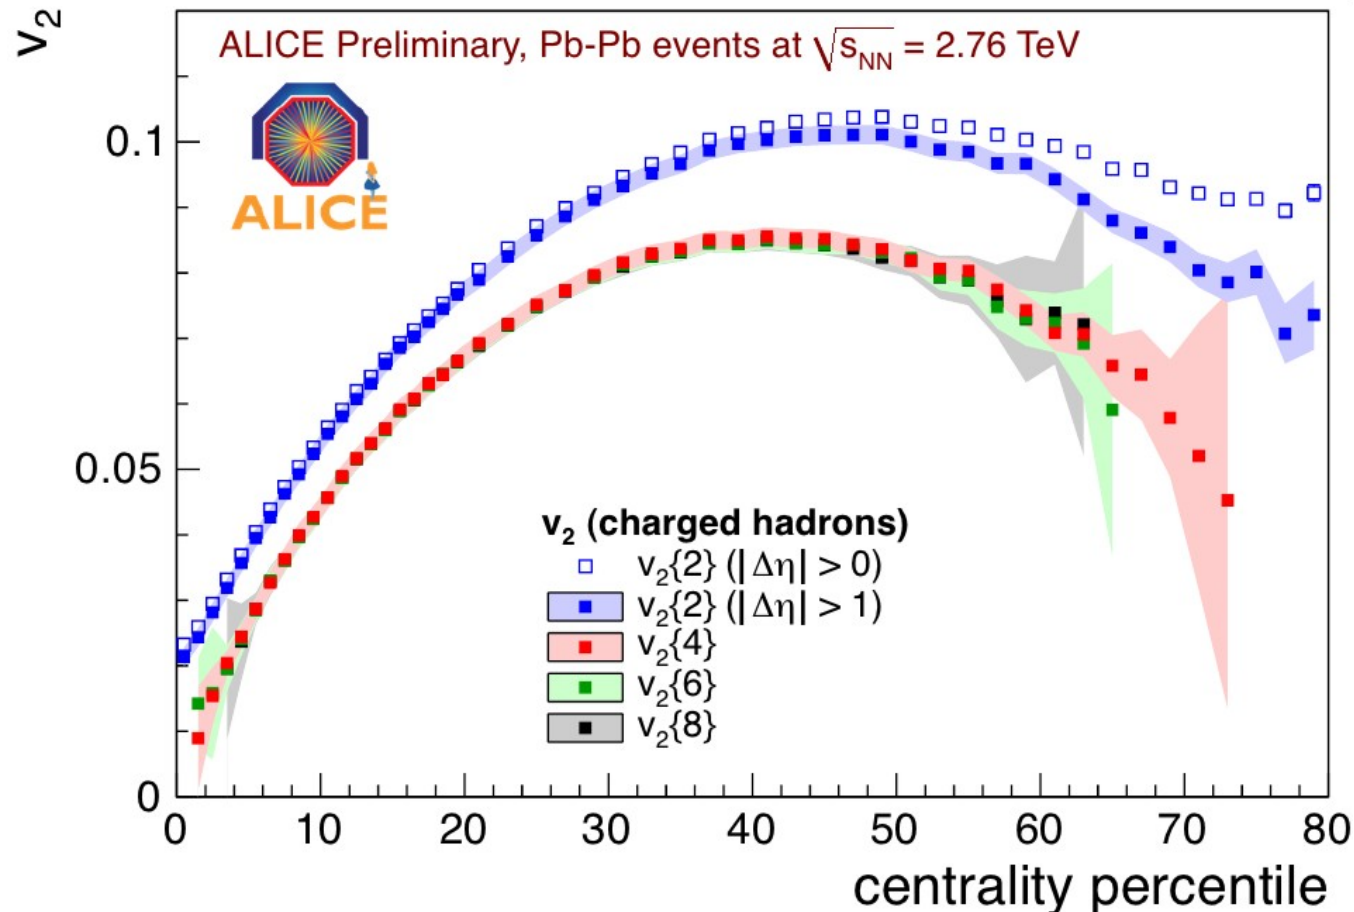

Two-particle correlation landscape (LHC) 20

ATLAS, prelim.

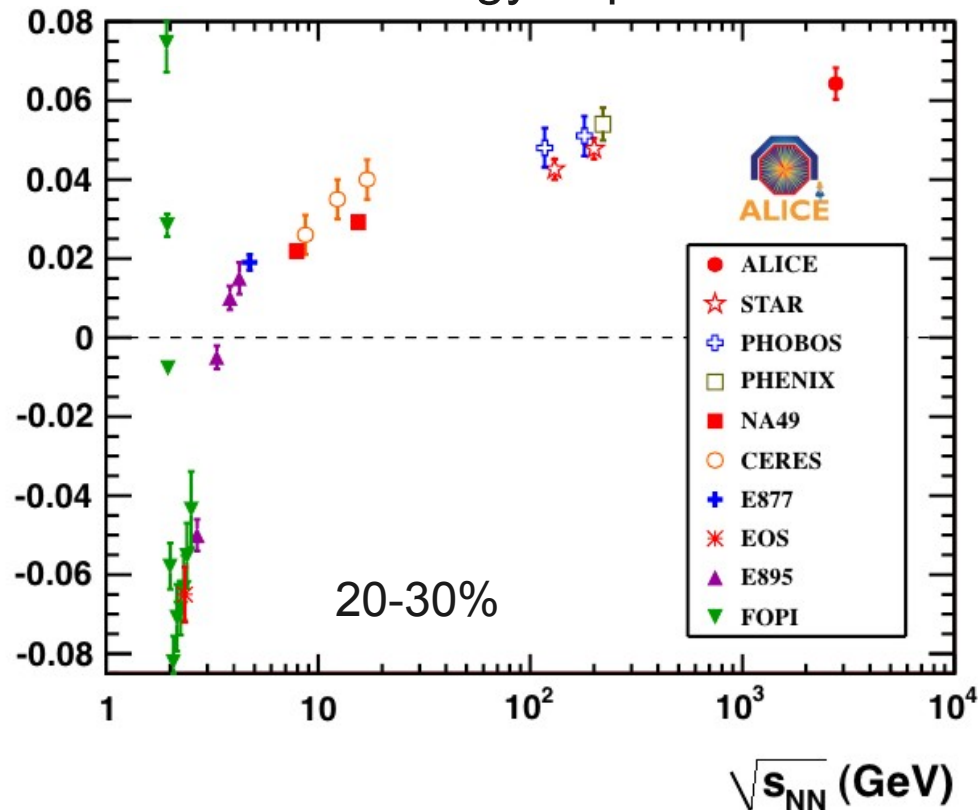

$2 < p_t^{\text{trigger}}, p_t^{\text{associated}} < 3 \text{ GeV}/c$

A.Bilandzic for ALICE, QM'11

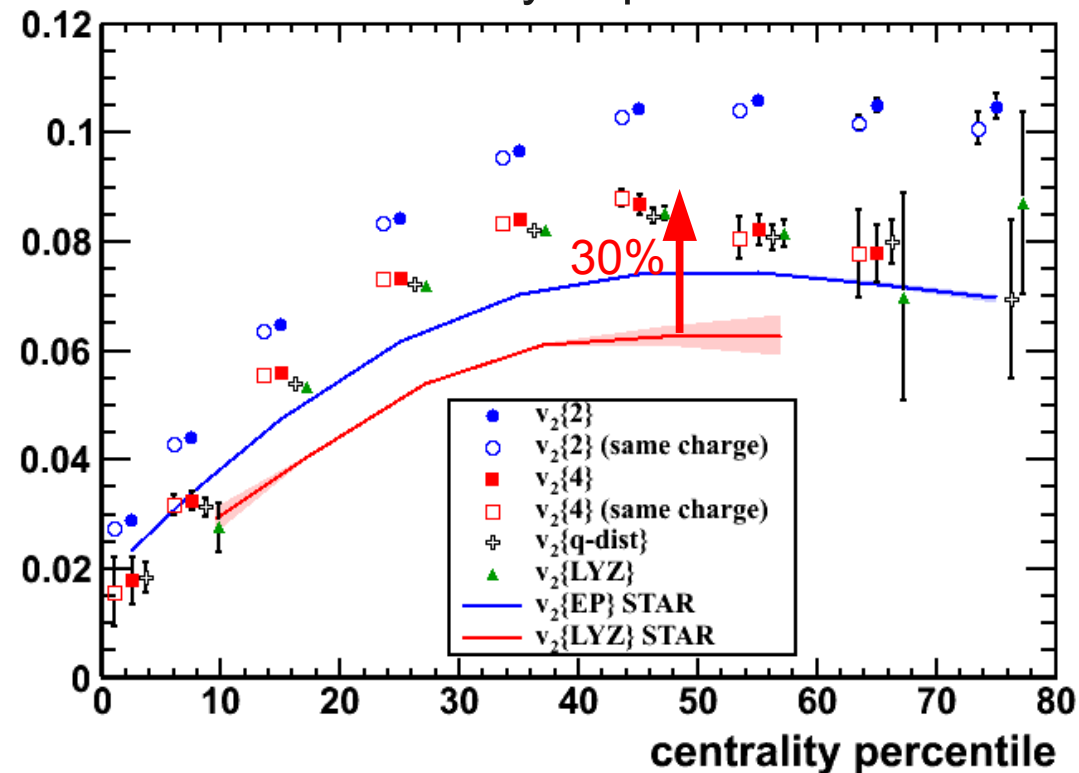

Multi-particle correlations (cumulant) studies extract the genuine multi-particle correlation

Collision energy dependence

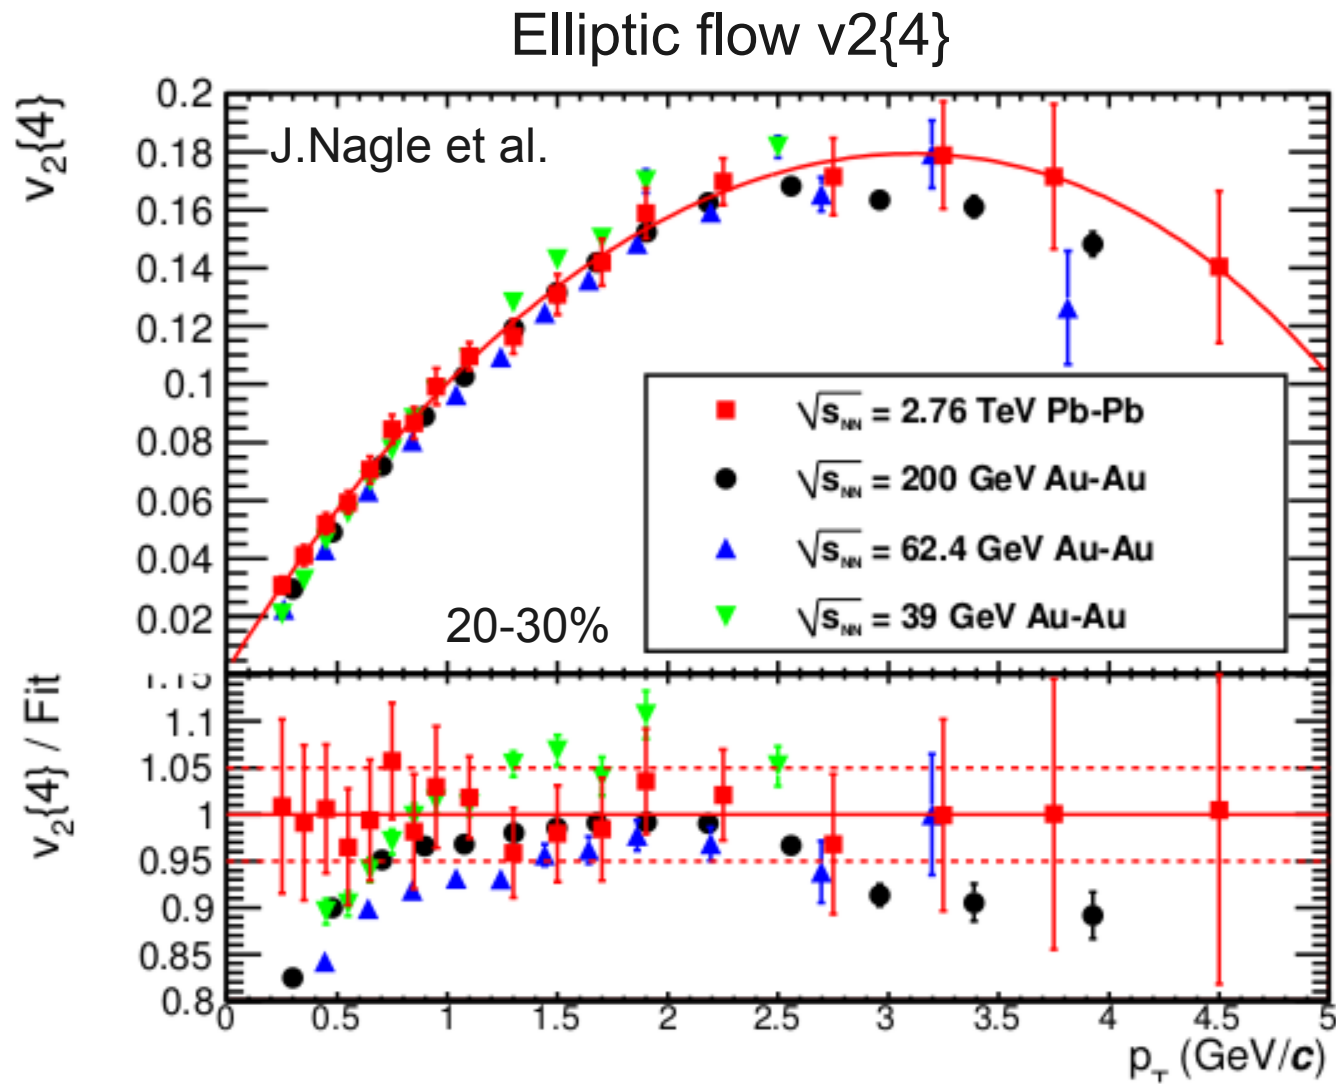

Centrality dependence

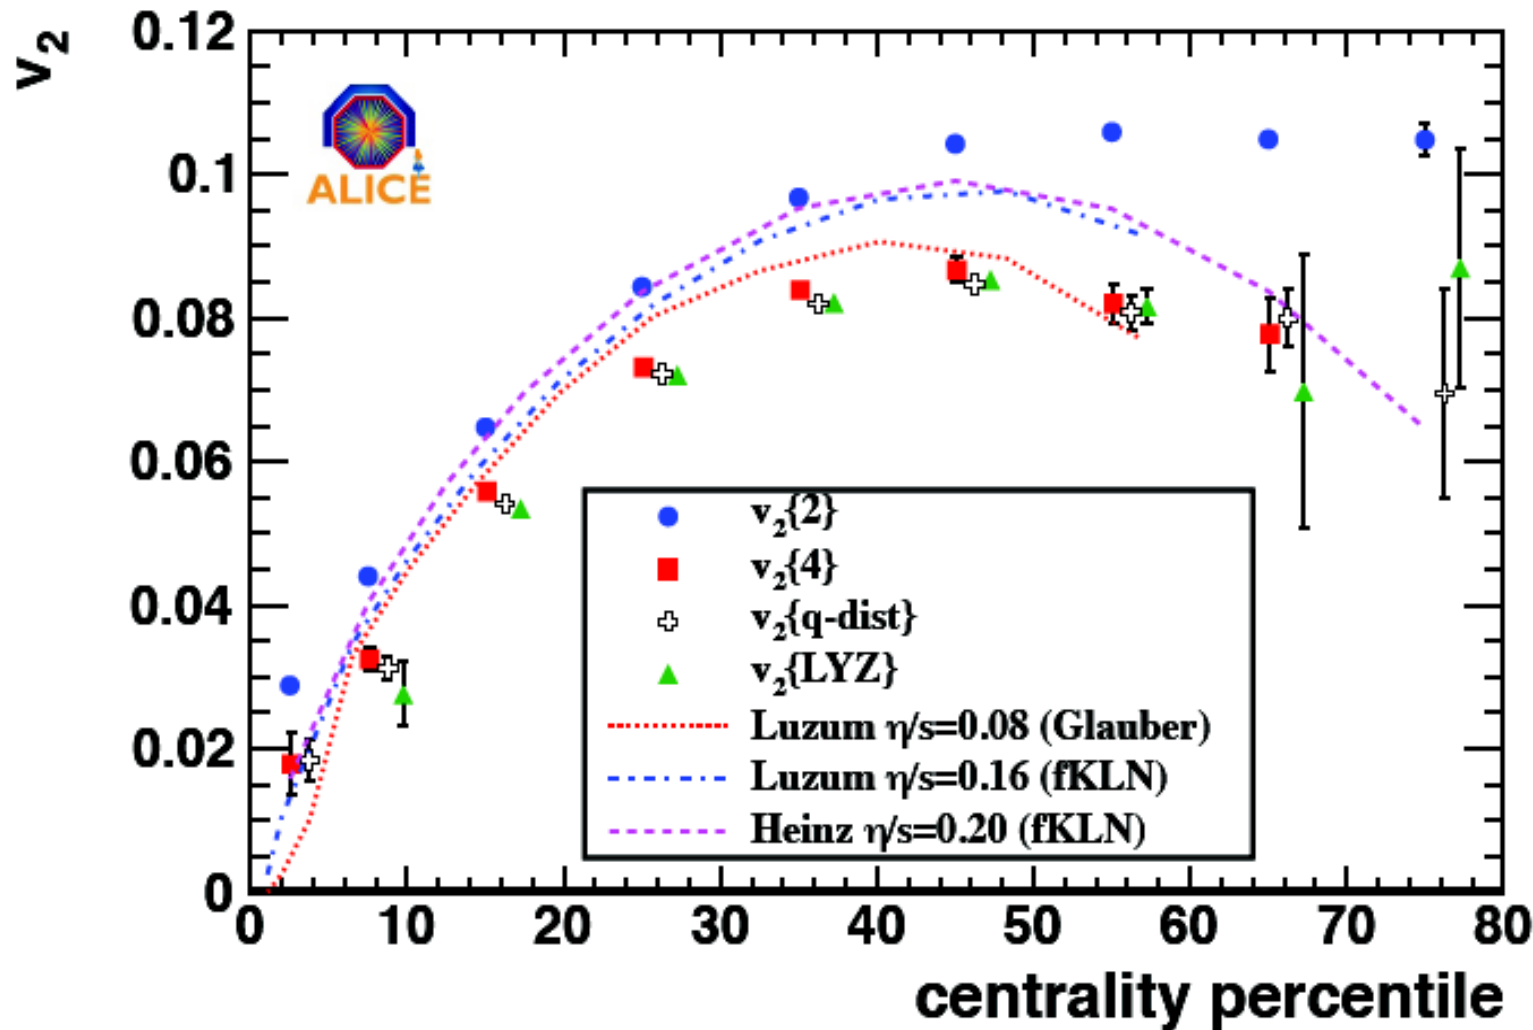

Integrated v_2 : **30% increase** from 0.2 TeV (STAR) to 2.76 TeV (ALICE)
Over all centrality classes, due to the increase of $\langle p_T \rangle$

No qualitative change in the observable at the LHC

Remarkable precision across four systems and experiments.

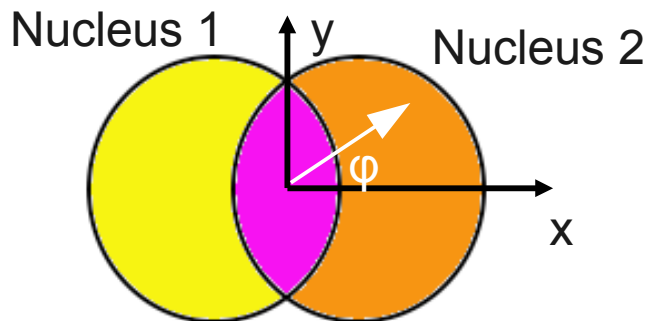

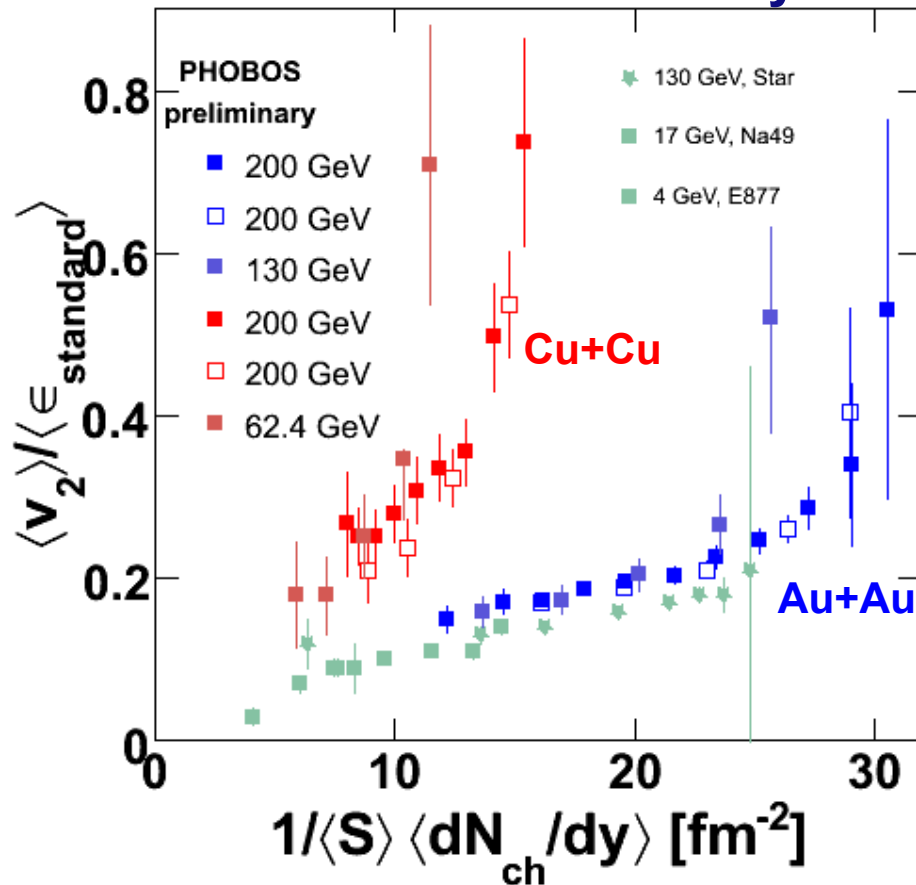

Calculation:
M.Luzum,
arXiv:1011.5173

Increase well within the range of viscous hydro predictions

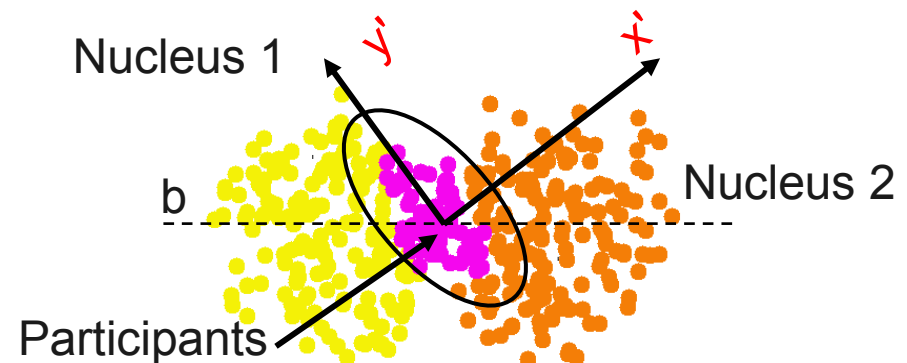

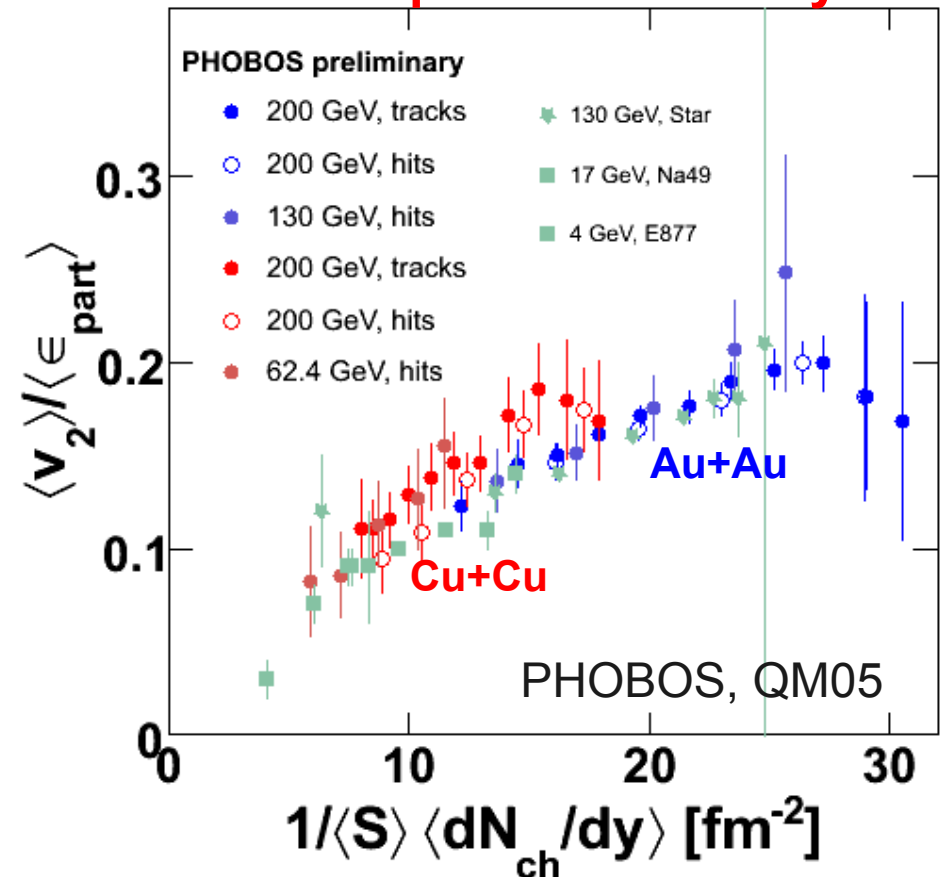

Importance of initial state fluctuations

25

Standard Eccentricity

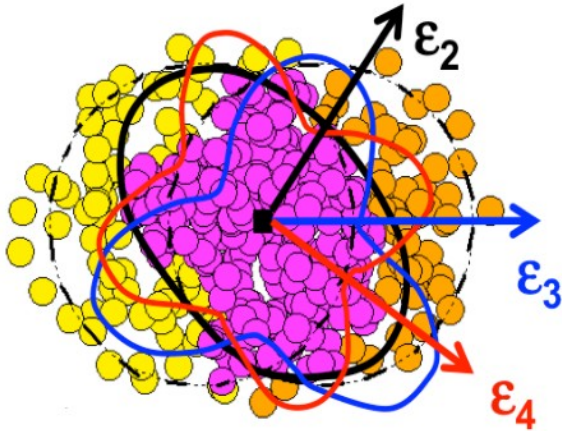

Participant Eccentricity

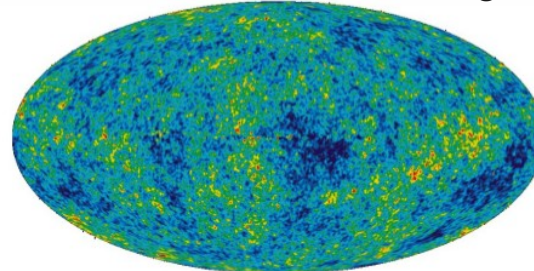

Higher azimuthal harmonics

26

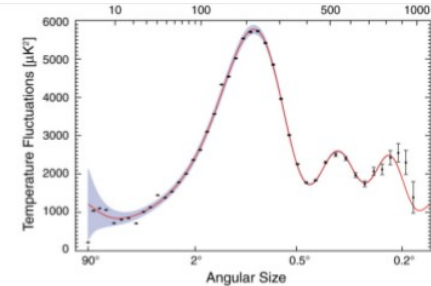

Analogous to power spectrum extracted from cosmic microwave background radiation

B.Alver, G.Roland
P.Sorenson, 2010

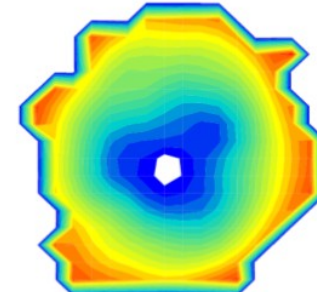

WMAP, Astrophys.J.Suppl.170:288,2007

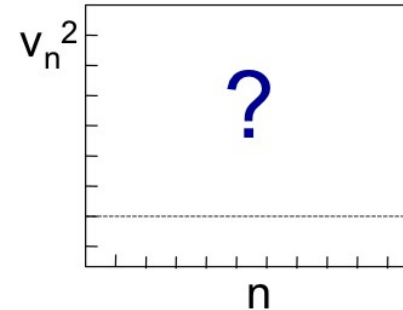

$$N_{pairs} \propto 1 + 2v_1^2 \cos \Delta\varphi + 2v_2^2 \cos 2\Delta\varphi + 2v_3^2 \cos 3\Delta\varphi + 2v_4^2 \cos 4\Delta\varphi + \dots$$

Kowalski, Lappi and Venugopalan,
Phys.Rev.Lett. 100:022303

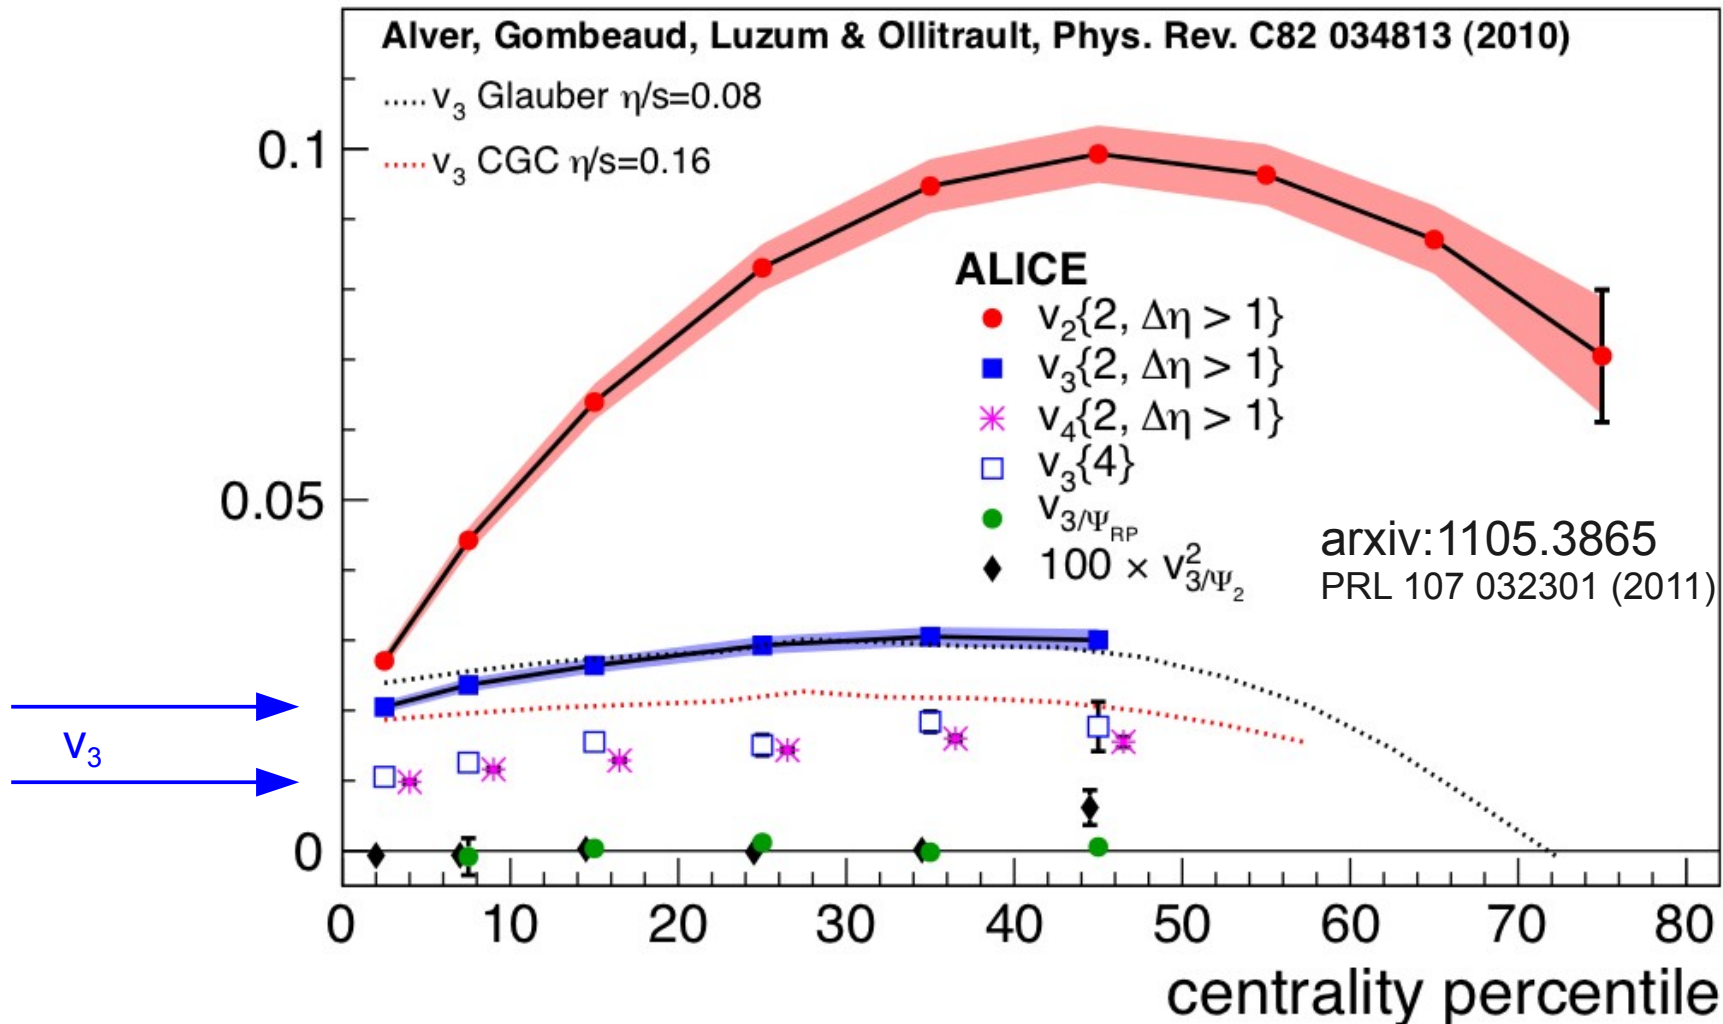

K. Werner, Iu. Karpenko, K.
Mikhailov, T. Pierog, arXiv:11043269

Initial spatial anisotropy not an almond, may lead to higher harmonic anisotropies in the final state

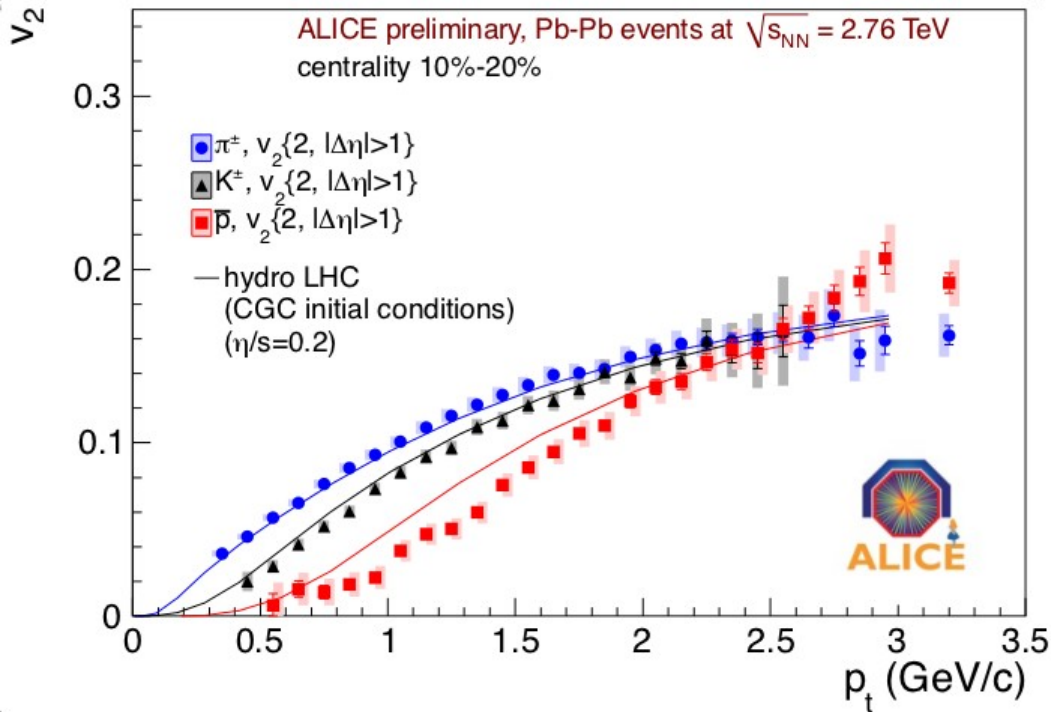

$$\frac{dN}{d\phi} \sim 1 + \underbrace{2v_2}_{\text{red}} \cos[2(\phi - \psi_2)] + \underbrace{2v_3}_{\text{blue}} \cos[3(\phi - \psi_3)] \\ + \underbrace{2v_4}_{\text{red}} \cos[4(\phi - \psi_4)] + \underbrace{2v_5}_{\text{blue}} \cos[5(\phi - \psi_5)] + \dots$$

S.Mohapatra/
E.Appelt Mon 2K

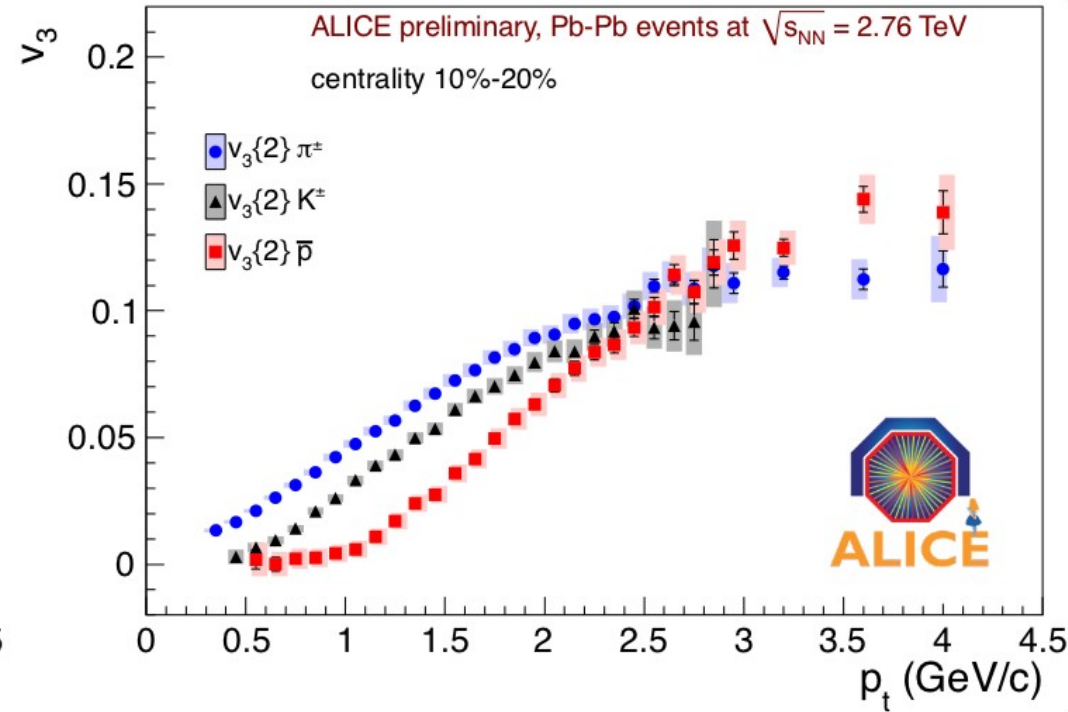

Sizeable triangular flow observed. As expected, centrality dependence is different to that of elliptic flow. Measurements vs reaction planes yield zero as it should if from fluctuations.

Elliptic flow

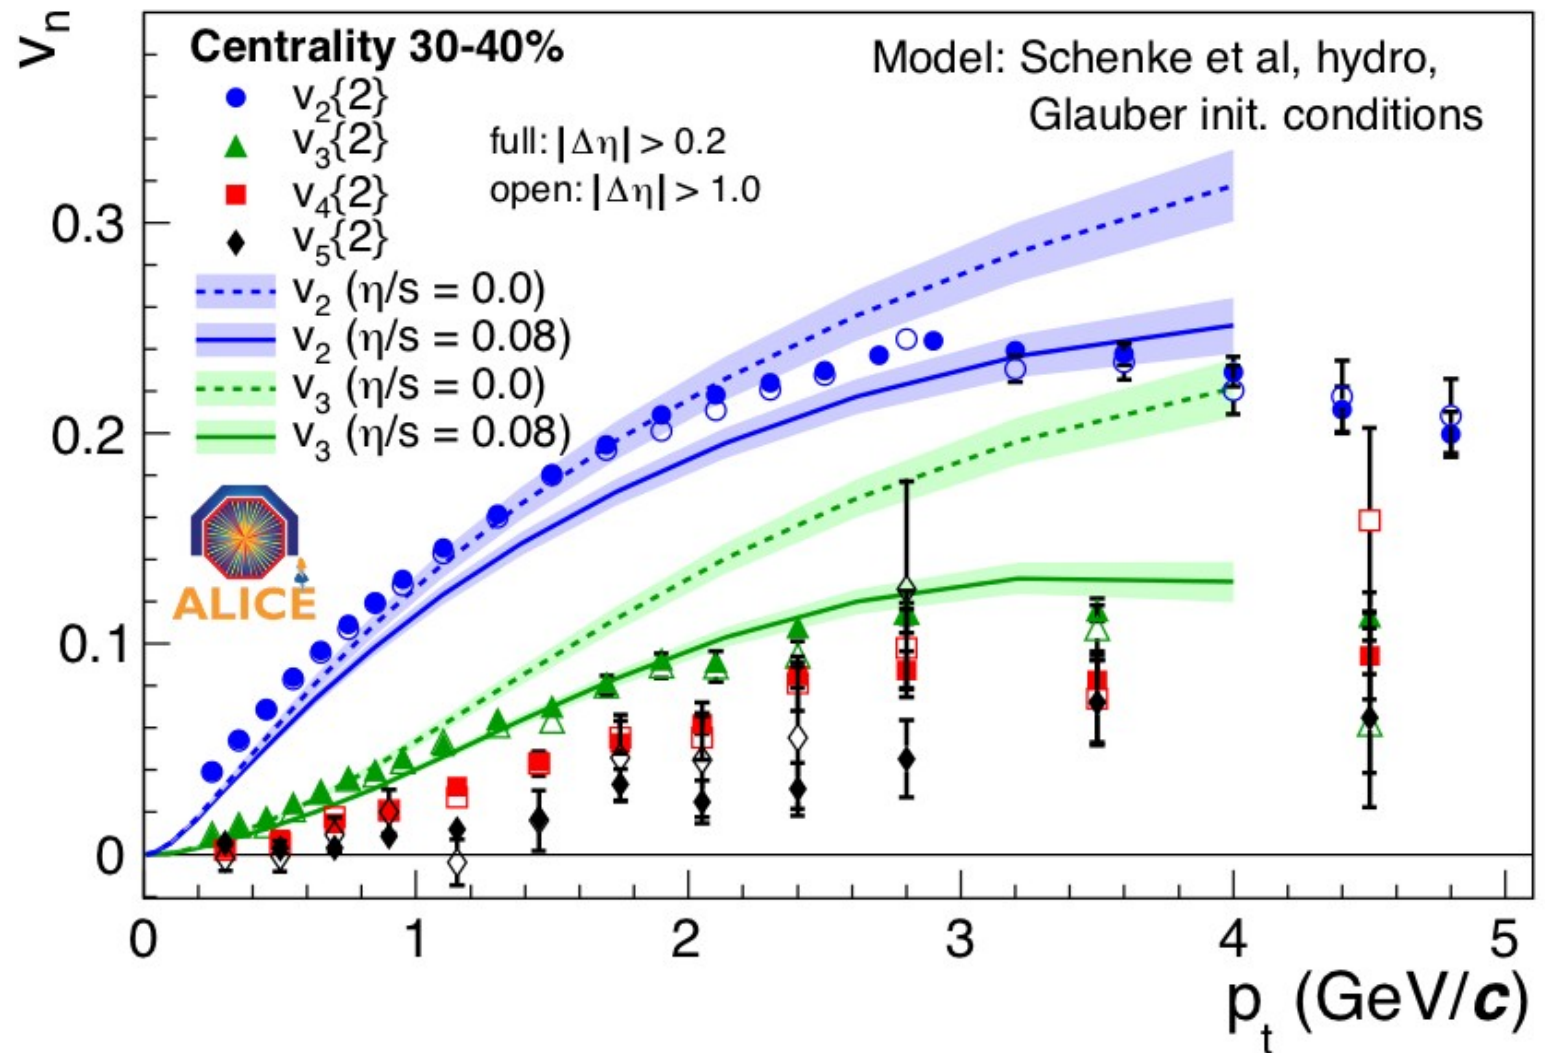

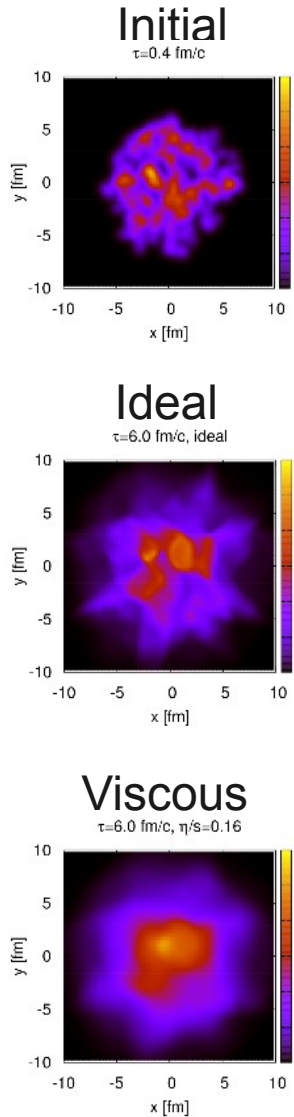

Triangular flow

Same mass splitting for v_3 as predicted for v_2 by hydro.

(Note also that the crossing between (anti-) protons and pions happens at the same p_T which for v_2 was considered a sign of recombination.)

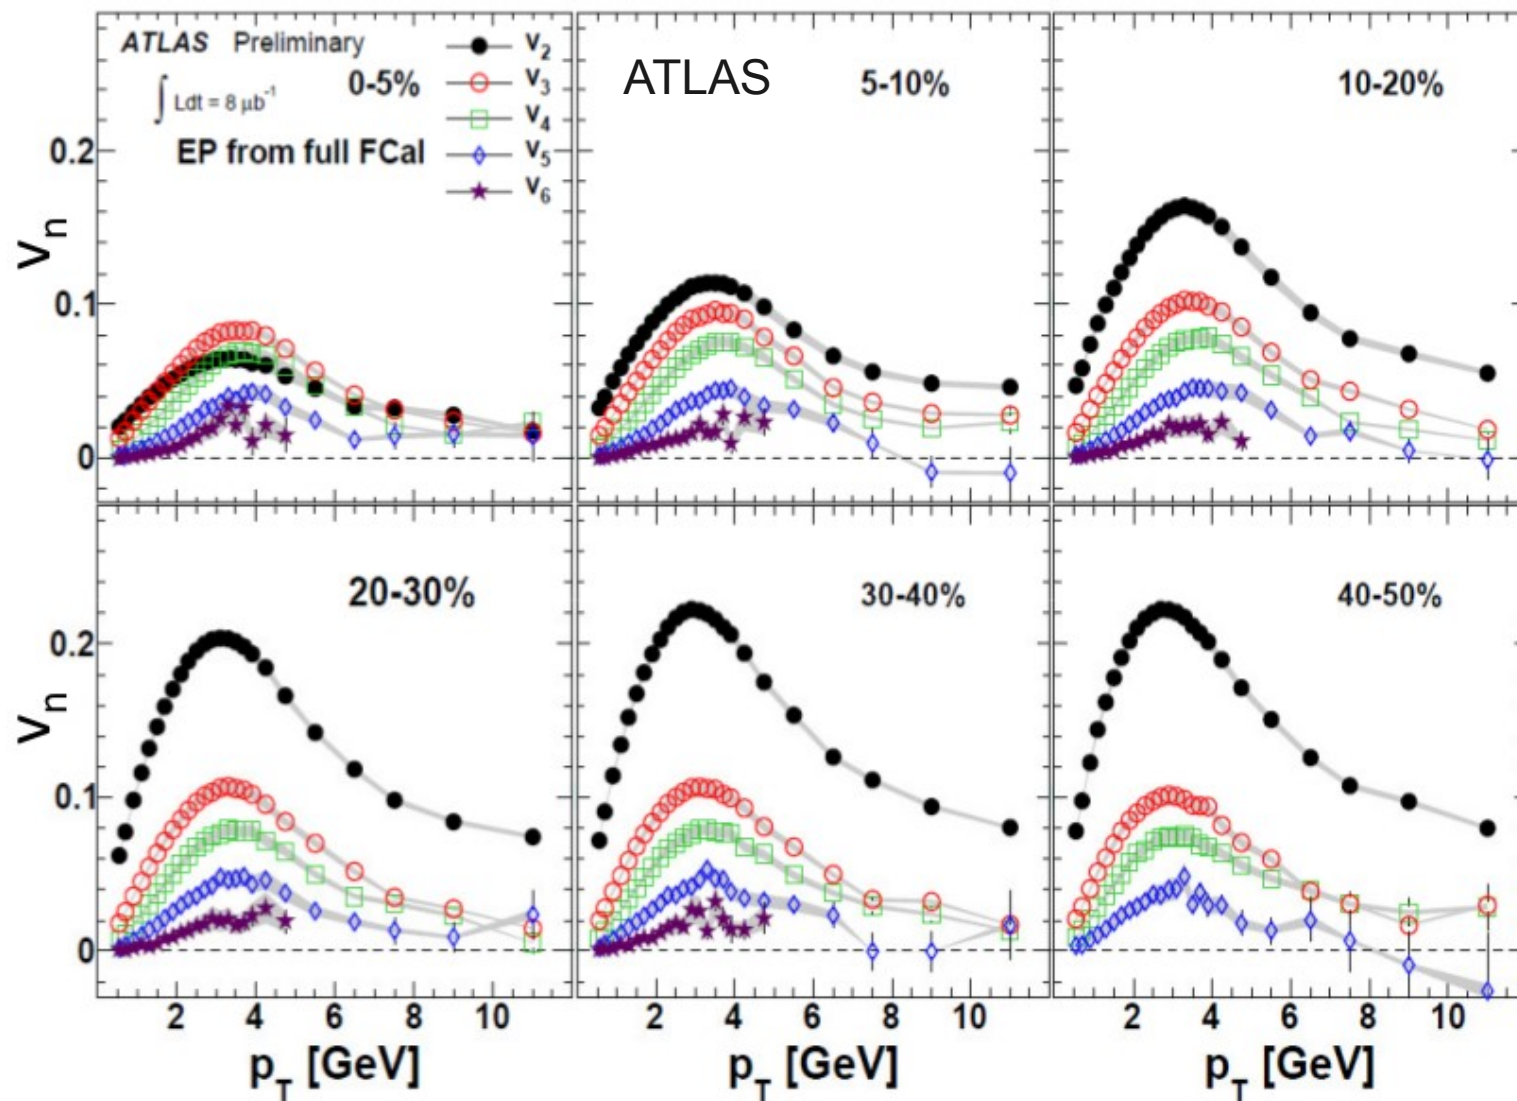

Fluctuations, viscosity and e-by-e hydro 29

The overall dependence of v_2 and v_3 is described. However, not yet for a single η/s value. More constraints on initial conditions provided by v_3 and higher harmonics.

Many higher moments measured

30

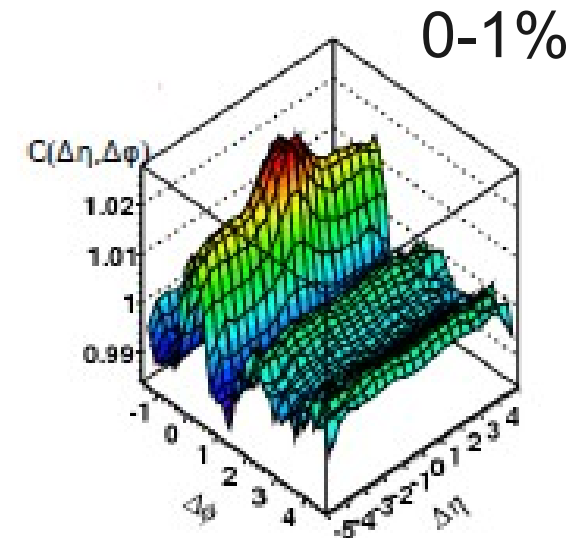

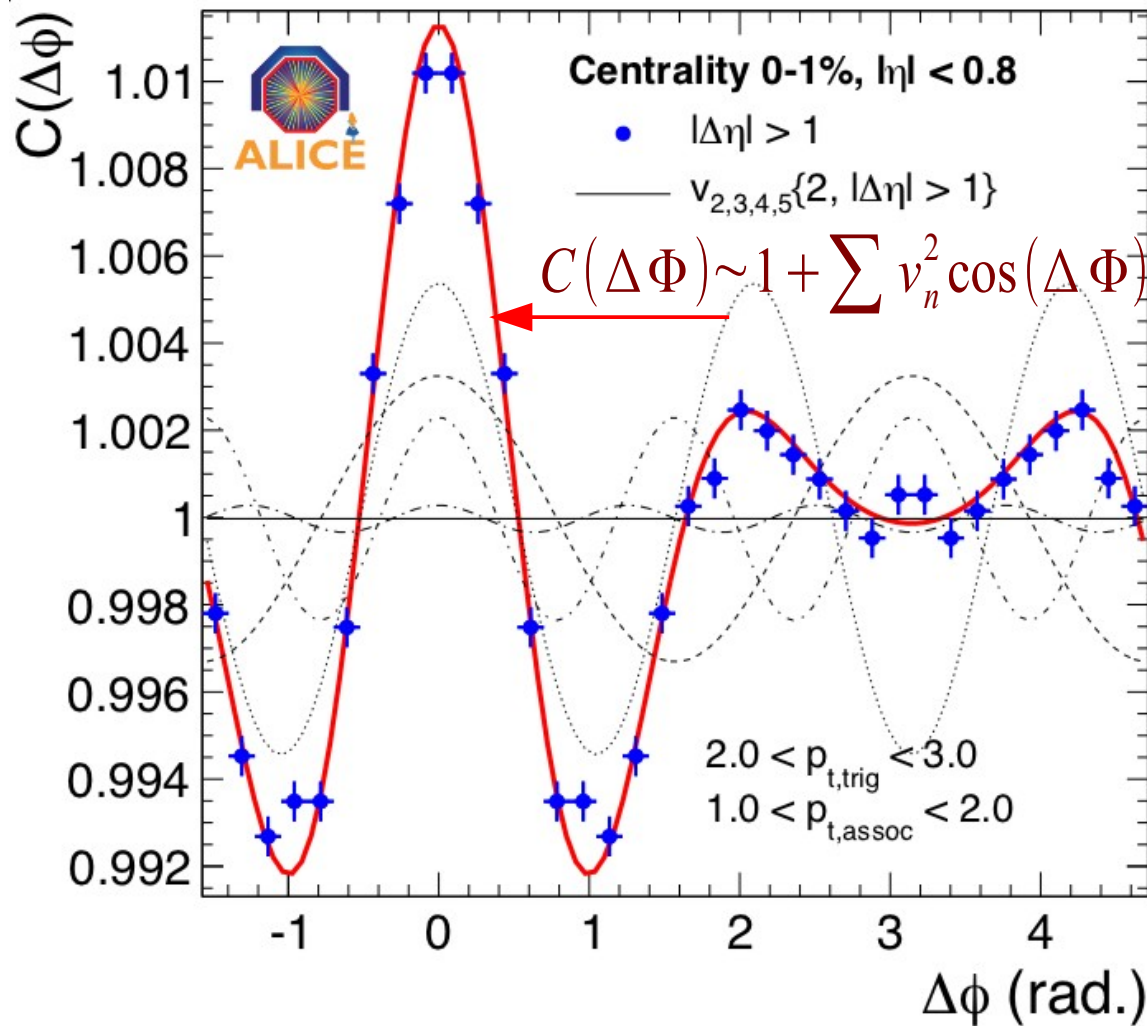

Higher moments are measured up to v_6 . Power spectrum of QGP. (Results by all collaborations at RHIC/LHC.)

“Death of ridges and cones”

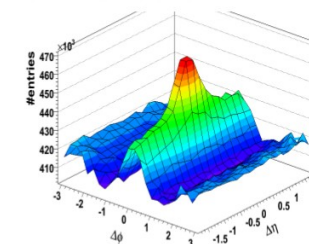

31

arxiv:1105.3865, PRL 107 032301 (2011)

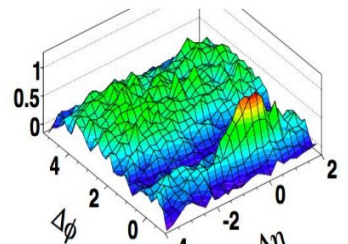

Intriguing ridge structure at RHIC

STAR Au+Au 0-10%

PRC 80 (2009) 64912

PHOBOS Au+Au 0-30%

PRL 104, 062301 (2010)

Structures seen in two particle correlations (reported mainly at RHIC) are naturally explained by measured anisotropic flow coefficients.

Where does the decomposition break? 32

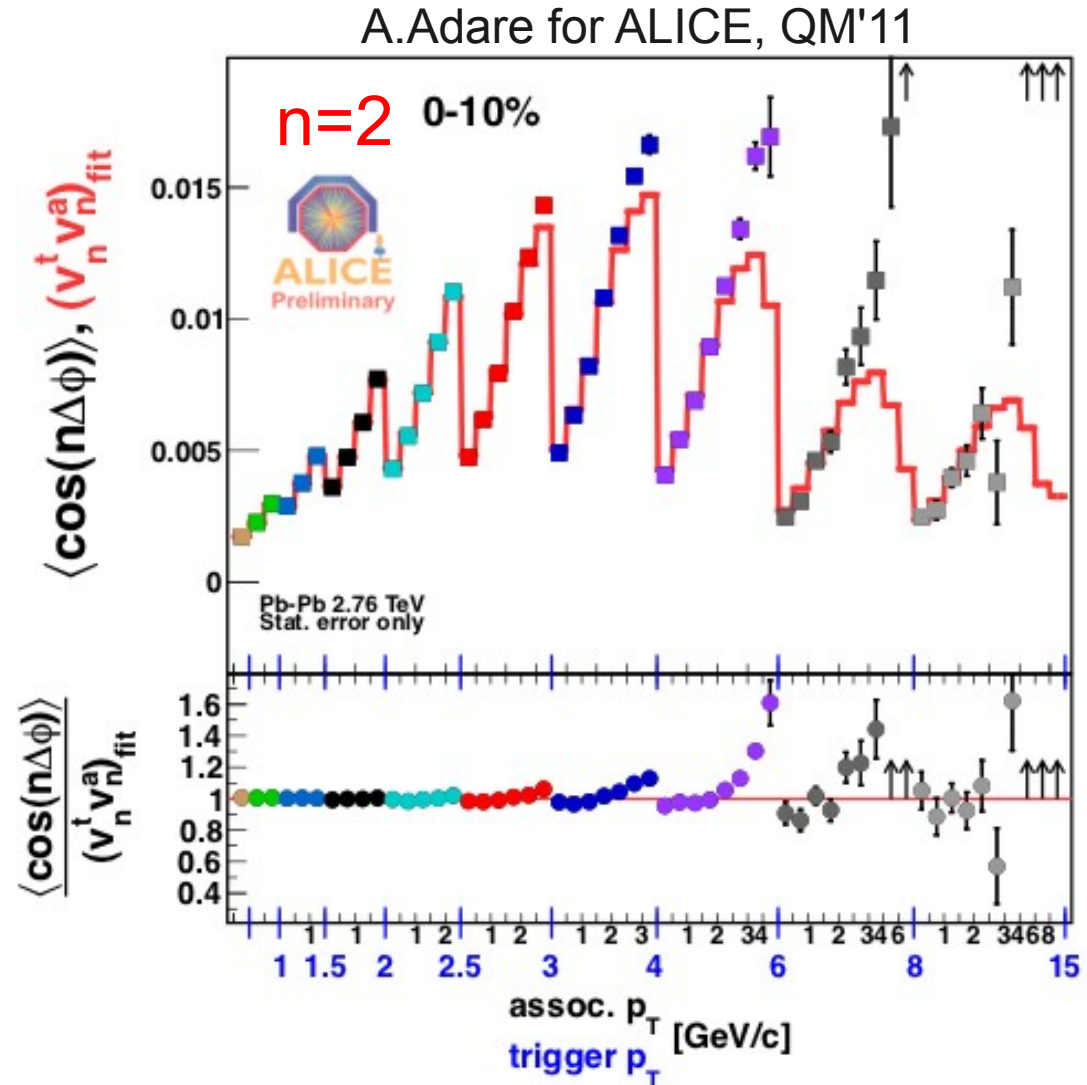

$$\frac{dN^{\text{pairs}}}{d\Delta\phi} \propto 1 + \sum_n 2V_{n\Delta}(p_T^t, p_T^a) \cos(n\Delta\phi)$$

$$\frac{dN}{d\phi} \propto 1 + \sum_n 2v_n(p_T) \cos(n(\phi - \Psi_n))$$

If bulk flow then:

$$V_{n\Delta}(p_T^t, p_T^a) = v_n(p_T^t) v_n(p_T^a)$$

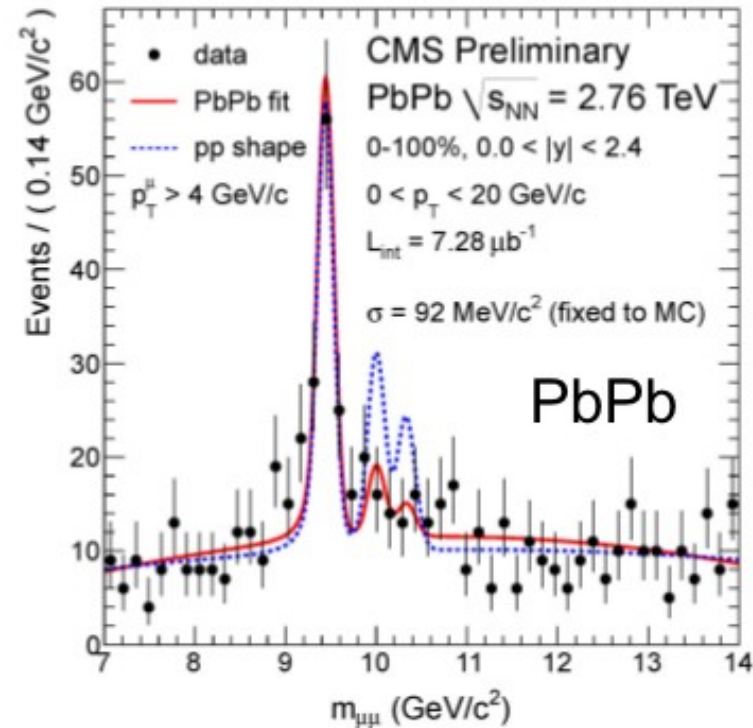

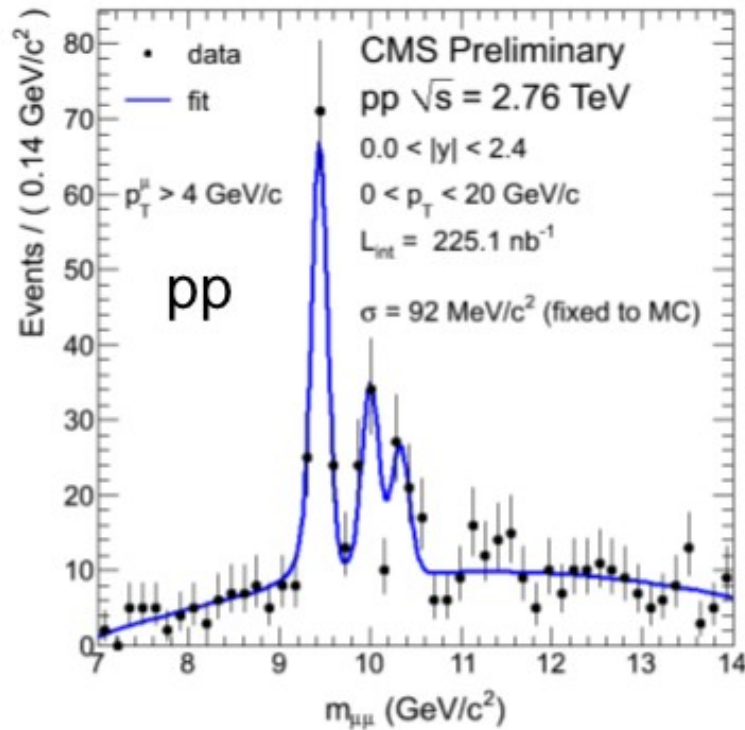

Perform global fit for each harmonics

Two particle correlations are well described via bulk flow decomposition up to about 4 GeV. Similar for other harmonics (except v_1). Challenge the jet heating picture (next talk)?

Melting of Upsilon (2S,3S)

33

$$\Upsilon(2S + 3S)/\Upsilon(1S)|_{pp} = 0.78^{+0.16}_{-0.14} \pm 0.02$$

$$\Upsilon(2S + 3S)/\Upsilon(1S)|_{PbPb} = 0.24^{+0.13}_{-0.12} \pm 0.02$$

$$\frac{\Upsilon(2S + 3S)/\Upsilon(1S)|_{PbPb}}{\Upsilon(2S + 3S)/\Upsilon(1S)|_{pp}} = 0.31^{+0.19}_{-0.15} \pm 0.03$$

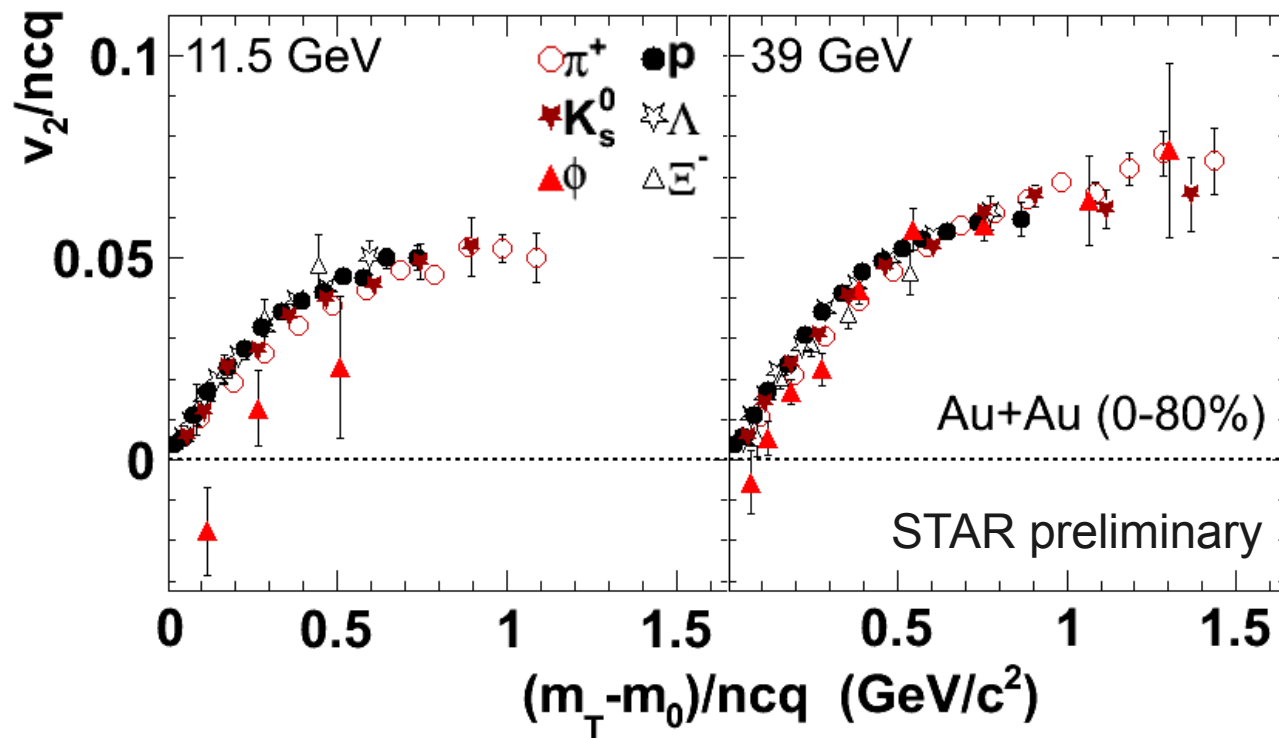

Direct access to the deconfined matter state? Stay tuned
Melting temperatures from the lattice are about 1.2 and 1.6 T_c .

- Exciting and stimulating time in our field with fruitful interplay of heavy-ion experiments at RHIC and LHC.
 - Characterization of LHC bulk properties well underway
 - No big picture changes (unlike the transition from SPS to RHIC)
 - Also first results from beam-energy scan (not discussed)
- Tremendous progress in the measurement of the QGP viscosity
 - The most perfect known fluids are the coldest and the hottest
 - QGP power spectrum (V_n) from fluctuations extracted
 - Expected to provide further constraints on η/s
 - Too early to conclude about precise value of η/s at the LHC

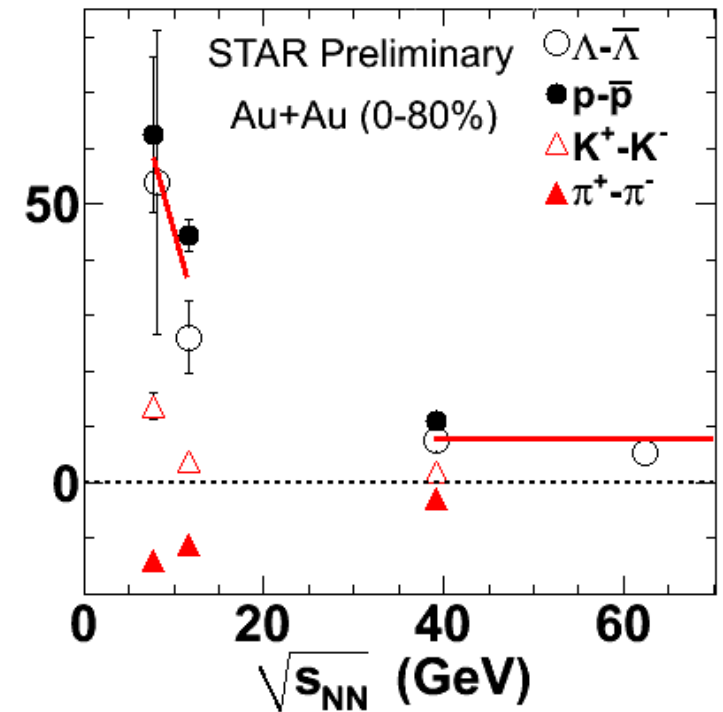

Special thanks to ALICE, ATLAS, CMS, STAR+PHENIX collaborations for their exiting new results and apologies to what I could have not shown for space-time restrictions.

Number of quark scaling (Beam-Scan) 36

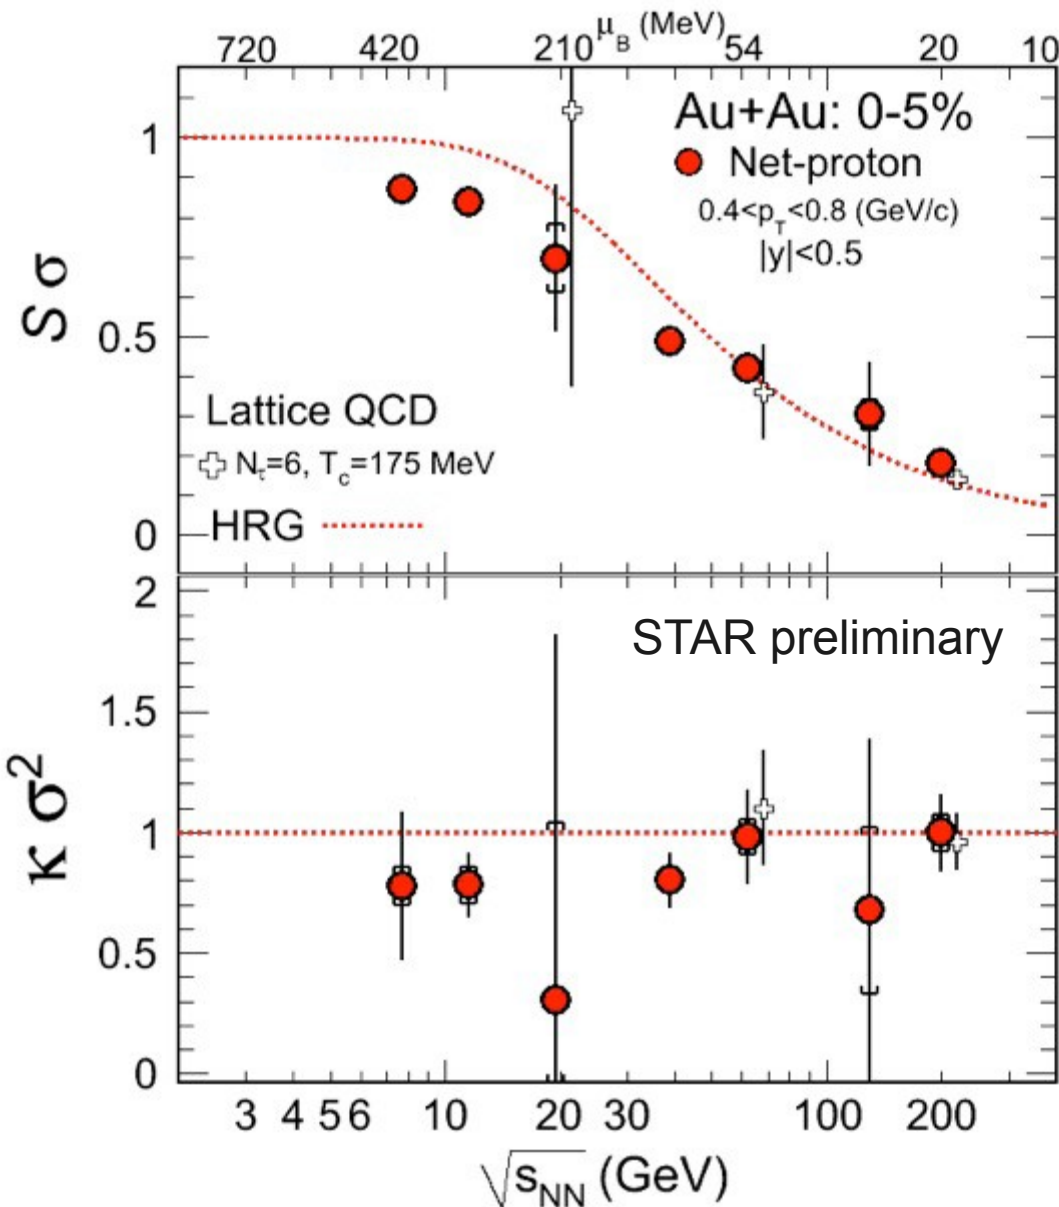

v_2 scaled with number of quark

$[v_2^p - v_2^{\bar{p}}]/v_2^p, \%$

- v_2 of ϕ meson does not follow the trend for other hadrons at 11.5 GeV
- Significant difference between baryon/anti-baryon v_2 @ 7.7 & 11.5 GeV
- No scaling between particles and anti-particles

Moments of net proton distribution (χ):

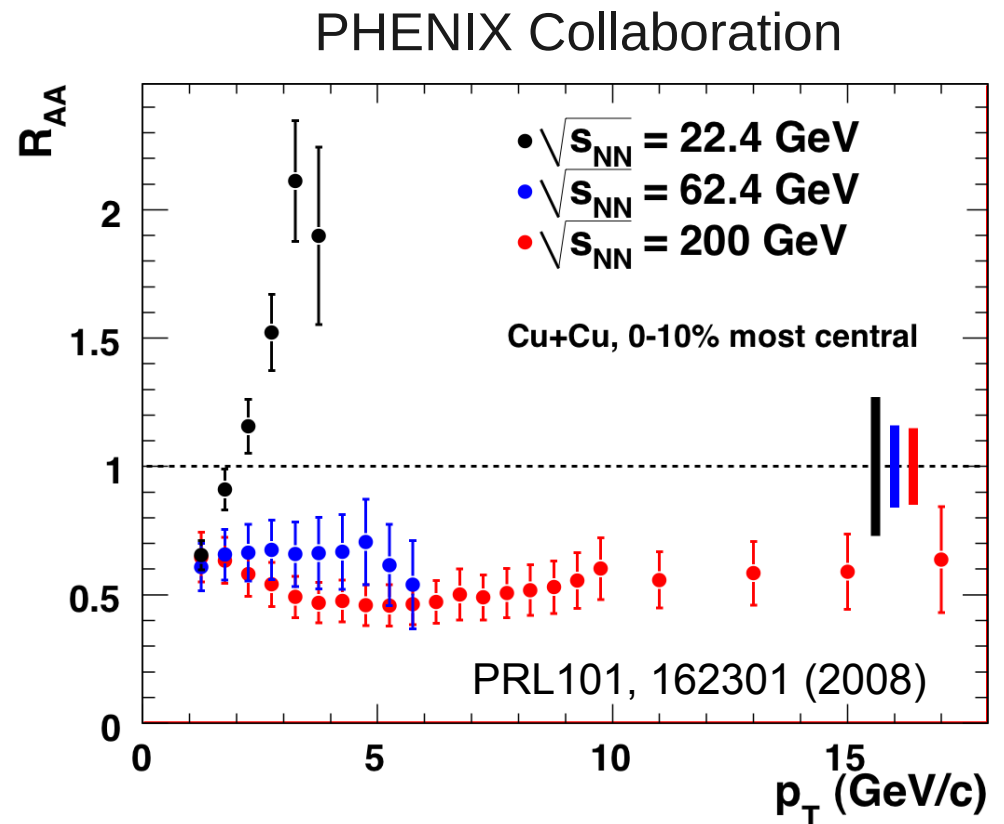

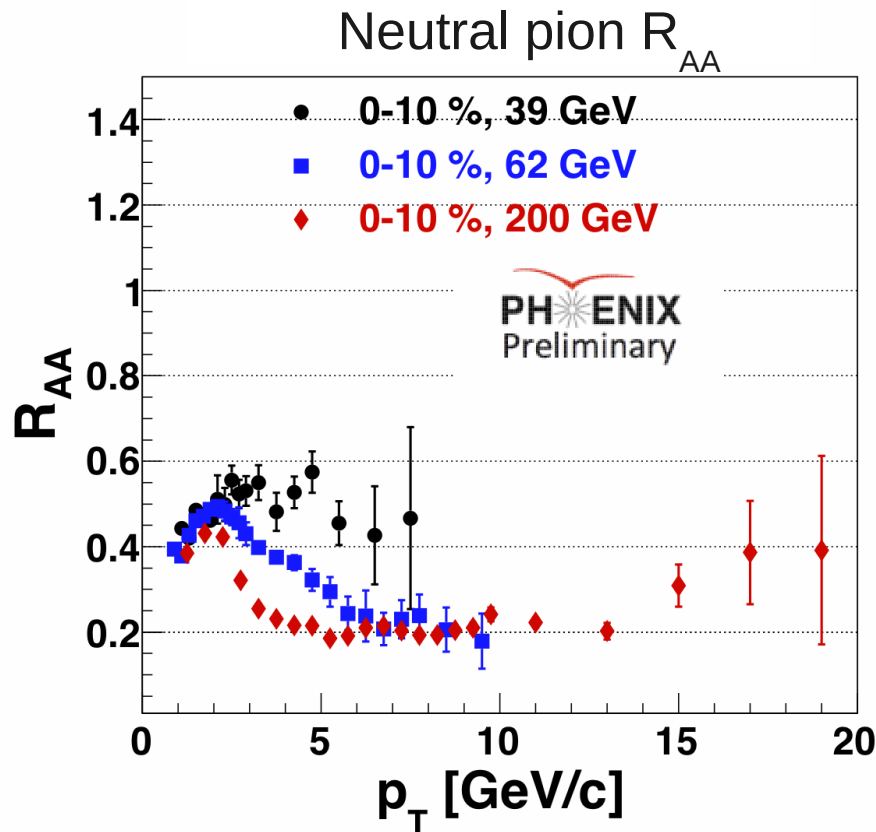

- 1st - mean, 2nd - variance (σ^2)
- 3rd - skewness (S), 4th - kurtosis (k)

- Connected to hydrodynamic susceptibilities
- Sensitive to the correlation length of the system

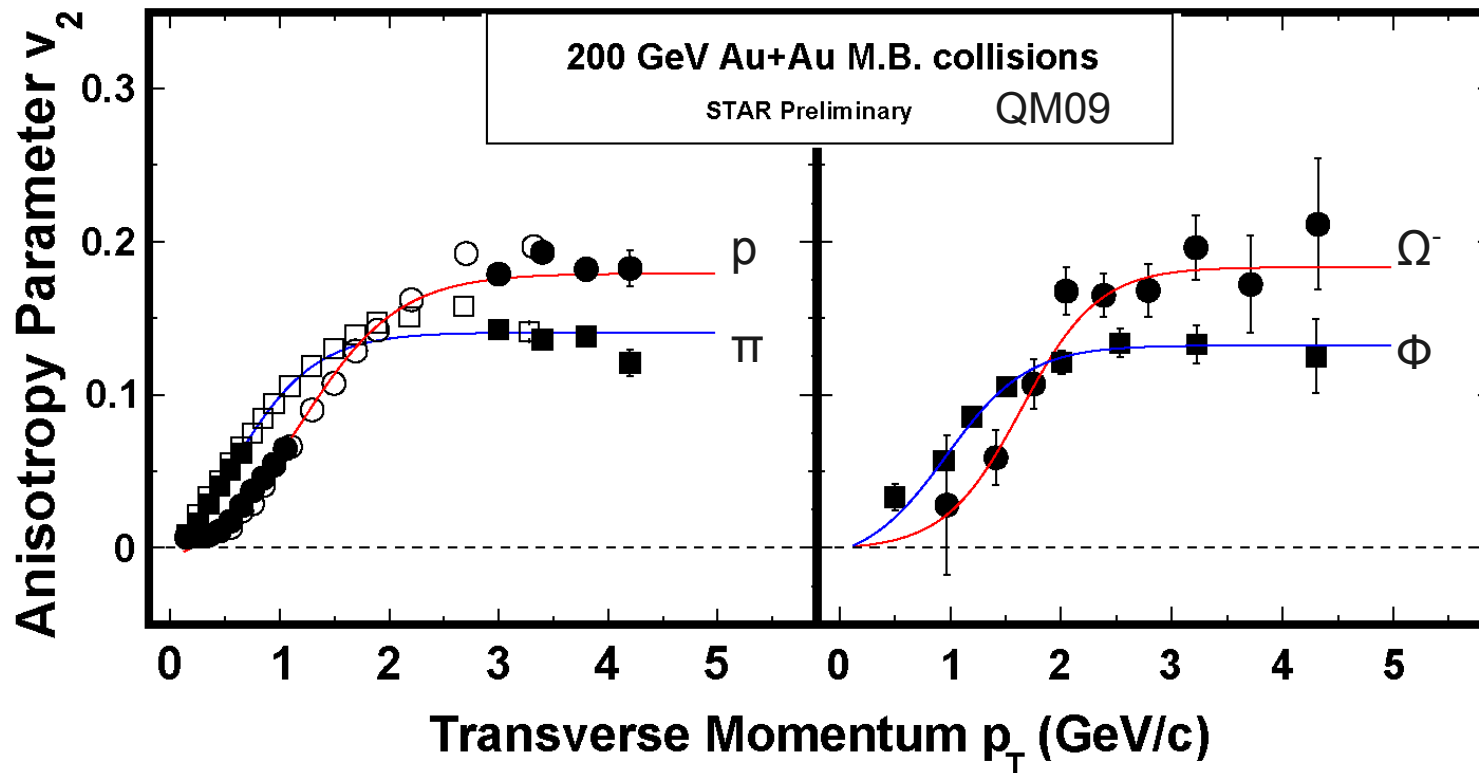

$$S\sigma = \chi^{(3)} / \chi^{(2)} \quad k\sigma^2 = \chi^{(4)} / \chi^{(2)}$$

- Consistent with Lattice QCD and Hadron Resonance Gas (HRG) model at higher energies
- Deviates from HRG below 39 GeV

Change in R_{AA} between 22.4 and 39 GeV 38

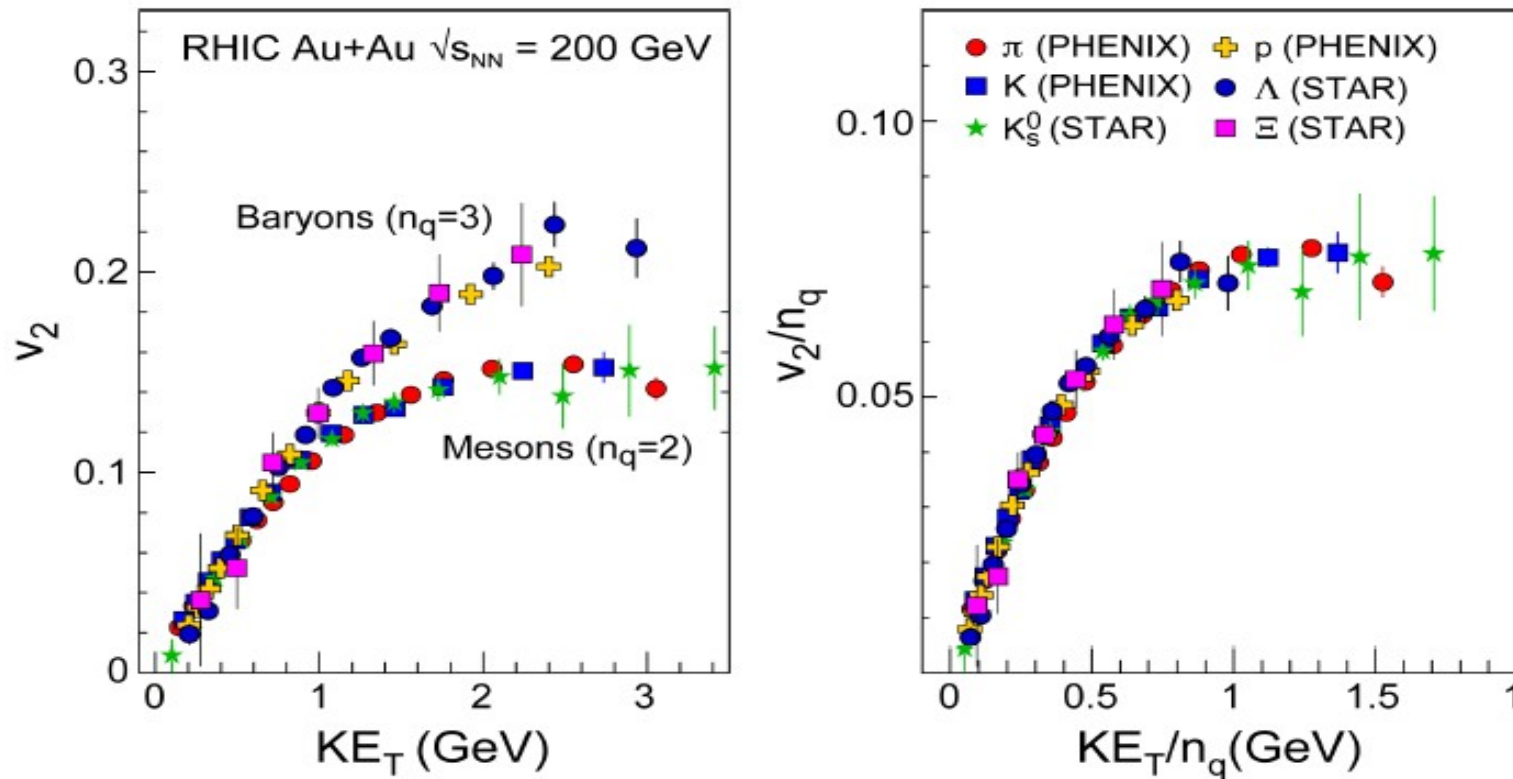

- Suppression $p_t > 3$ GeV/c consistent with parton energy loss at 62.4, 200 GeV:
- No suppression at 22.4 GeV
Enhancement consistent with Cronin enhancement
- Some hints from Beam Energy Scan program at RHIC on critical points between 7 and 20 GeV - **stay tuned!**

Partonic collectivity at RHIC:
Heavy multi-strange particles flow as protons and pions

Constituent quark scaling

40

All particles flow as if frozen out from a flowing soup of constituent quarks.

Two-particle cumulant

$$v\{2\} = \sqrt{\langle \cos(\phi_1 - \phi_2) \rangle}$$

Measures:

$$v\{2\}^2 = \langle v \rangle^2 + \sigma_{v_2}^2 + \delta$$

$$v \gg 1/\sqrt{M}$$

Four-particle cumulant

$$v\{4\} = \left(2 \langle \cos(\phi_1 - \phi_2) \rangle^2 - \langle \cos(\phi_1 + \phi_2 - \phi_3 - \phi_4) \rangle \right)^{1/4}$$

Measures:

$$v\{4\}^2 = \langle v \rangle^2 - \sigma_{v_2}^2$$

$$v \gg 1/M^{3/4}$$

$$v\{\text{subEP}\} = \frac{\langle \cos(\phi - \psi_A) \rangle}{R}$$

$$R = \sqrt{\langle \cos(\psi_A - \psi_B) \rangle}$$

Measures:

$$v\{\text{subEP}\}^2 = \langle v \rangle^2 + (1 - f(R)) \sigma_{v_2}^2 + (1 - 2f(R)) \delta$$

NB: For simplicity, n (as index and in cos terms) dropped

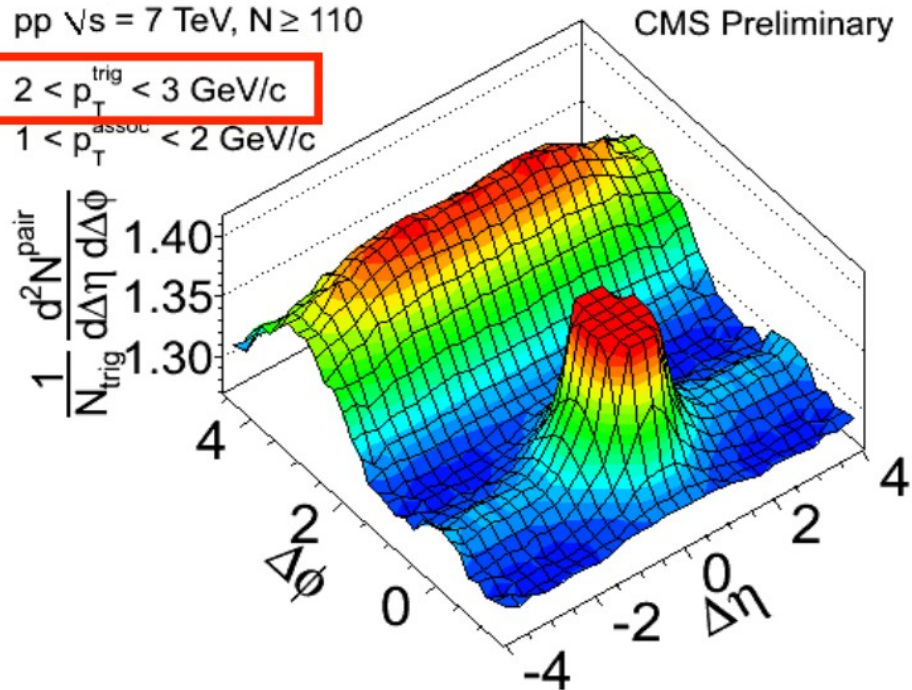

Ridge in high-multiplicity p+p at LHC

42

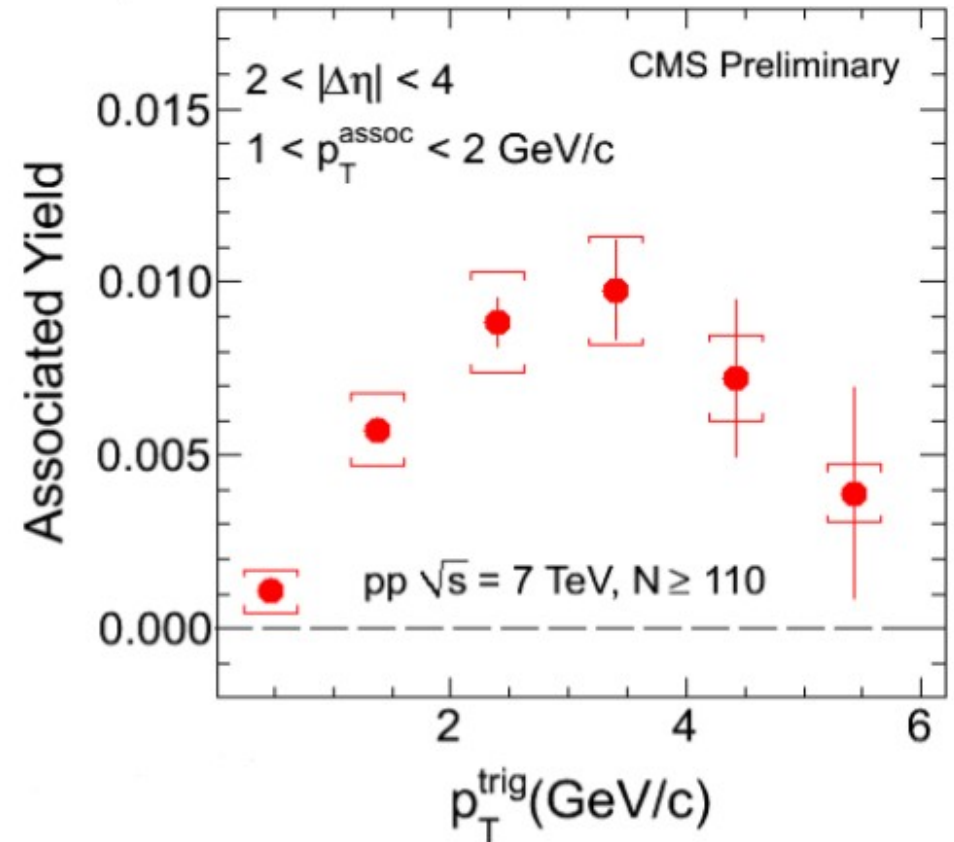

pp $\sqrt{s} = 7$ TeV, $N \geq 110$

$2 < p_T^{\text{trig}} < 3$ GeV/c

$1 < p_T^{\text{assoc}} < 2$ GeV/c

Zero-Yield-At-Minimum in ridge region

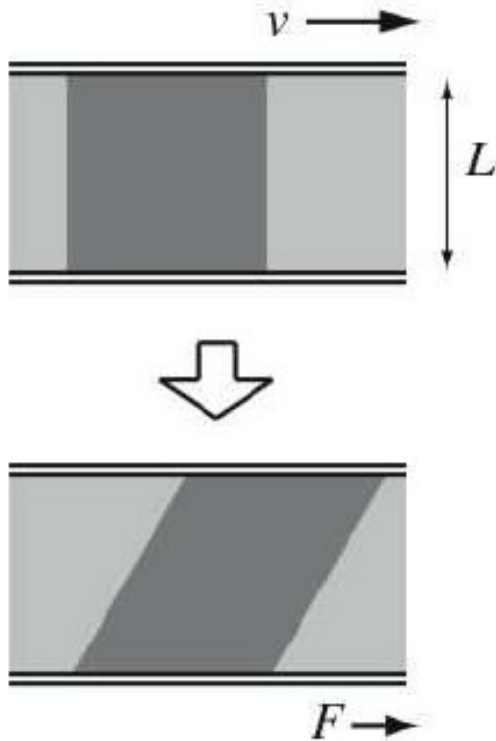

Observation of ridge in high density proton-proton collisions

Shear viscosity in fluids

43

Shear viscosity characterizes the efficiency of momentum transport

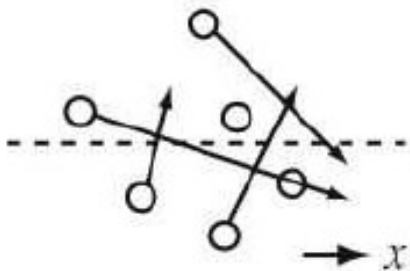

$$\frac{F}{A} = \eta \frac{v}{L}$$

quasi-particle
interaction cross
section

$$\eta = \rho \langle v \rangle \lambda_{mfp} \sim \left(\frac{1}{\sigma} \right)$$

Comparing relativistic fluids: η/s

- s = entropy density
- scaling param. η/s emerges from relativistic hydro eqns.
- generalization for non-rel. fluids: η/w (w =enthalpy)
(Liao and Koch, Phys.Rev. C81 (2010) 014902)

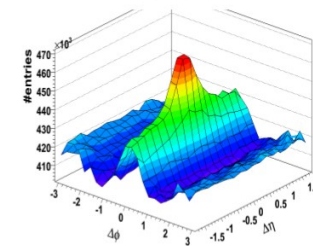

Large $\sigma \rightarrow$ small η/s
 \rightarrow Strongly-coupled matter
 \rightarrow "perfect liquid"
